

Update on ^{17}O evaluation and fast neutron evaluation for ^{181}Ta

M. Herman, T. Kawano, M. Paris
LANL/T-2

CSEWG-2022, February 17

Managed by Triad National Security, LLC for the U.S. Department of Energy's NNSA

Update on 170 system evaluation

M. Paris [M. Herman presenting]

$^{17}\text{O} \sim n+^{16}\text{O}, \alpha_0+^{13}\text{C}, n_1+^{16}\text{O}^*, n_2+^{16}\text{O}^{**}$

- Continuing efforts on ^7Li & ^9Be [reported elsewhere]
- ^{17}O
 - review of previous ENDF/B evaluations
 - ENDF/B-VI.8 (April, 2001) LANL $n+^{16}\text{O}$ evaluation (by Chadwick, Hale & Young): evaluation done prior to Harissopoulos 2005 data; ENDF/B-VI.8 is preferred by IAEA integral benchmarks
 - ENDF/B-VII.1 treated Harissopoulos 2005 as "definitive"
 - JENDL-4.0 adopted ENDF/B-VII.0 (prior to Harissopoulos 2005 data), which is equivalent to VI.8
 - added inelastic $^{16}\text{O}^*(0^+; 6.05 \text{ MeV})$ and $^{16}\text{O}^{**}(3^-; 6.13 \text{ MeV})$ inelastic channels to EDaf90 R-matrix configurations
 - augmented data deck:
 - more complete set of $^{16}\text{O}(n,\text{el})$ angular distributions and polarization data
 - $^{16}\text{O}(n,n_2)$ inelastic angular distributions
 - including $^{13}\text{C}(\alpha,n_0)$ and $^{13}\text{C}(\alpha,n_1)$ angular distributions 2021 data from Notre Dame
 - comparison with LENZ(2017) data from LANL (by Kuvín & Lee) with ENDF/B-VIII.0 parameters: good agreement below 6.25 MeV
 - new, preliminary evaluation compared with 2021 OU (Brandenburg & Meisel) and 1973 Bair & Haas data: significant improvement above $E_\alpha > 5.0 \text{ MeV}$ (previous upper limit)
 - performed consistency study of low energy (α,n_0) data
 - presently incorporating any missing data and investigating normalizations of Cierjacks' '68 and '83 datasets
 - writing ^{17}O system paper for Phys. Rev. C publication

^{181}Ta - fast neutron evaluation

M.Herman & T. Kawano

... a bit of motivation

- ENDF/B_VIII.0 description: “data file ...is part of a large collection of isotopic evaluations...not tested against experimental data ... only as good as the global quality of Talys. ”
- Tantalum is used for casting of plutonium peats at LANL PF-4. k_{eff} for this casting is 2-3 times more sensitive to inelastic, elastic and capture on Ta than to the respective reactions on Pu239 (LA-UR-19-31175)
- Isomers abound in residual nuclei produced in interaction of fast neutrons with Ta so it is relevant to Radchem (LA-UR-21-23034)
- Evaluation of the resolved and unresolved region by ORNL/NNL has been recently submitted to NNDC.

Experimental data for fast neutrons (100 keV - 20 MeV)

- Exceptional wealth of exp. data for practically mono-isotopic (99.99%) Ta181
 - cross sections:
 - total
 - elastic
 - inelastic scattering
 - capture
 - (n,p)
 - (n,2n)
 - (n, α), (n,t), (n, ^3He), (n,n α),
 - Angular distributions
 - elastic
 - inelastic
 - n and γ DE and DDX (+ p & α)
 - Several isomeric cross sections

Accession #

- Number of EXFOR datasets : 343
- Number of EXFOR quantities: 137
- EMPIRE makes 468 plots (!)

Extraordinarily well distributed measurements!

Concept of this evaluation

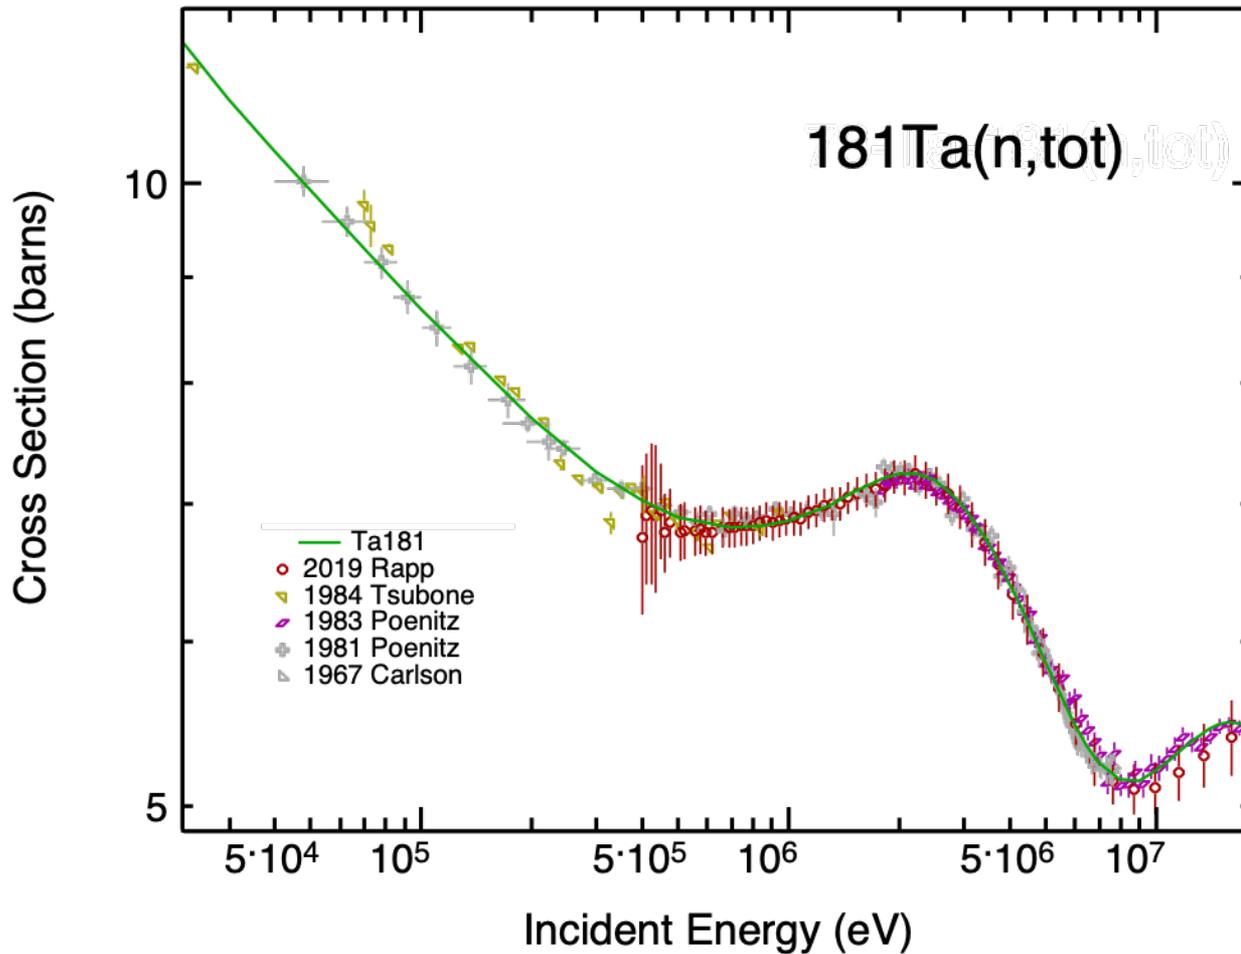

- Combine modeling of EMPIRE-3.2 with experimental data to produce a consistent picture of nuclear reactions considering “all” available differential and integral data.

CC optical model - total x-sec

- Ta181 is a strongly deformed and requires Coupled-Channels (CC)
- The RIPL-3 (#610) regional CC potential extends up to 200 MeV but it needs adjustments from 50 keV up to 20 MeV
- Two reliable and consistent measurements of total by Poenitz et al, covering entirely this energy range were used to refine the potential
- Fitting performed with Kalman filter resulted in rather minor corrections

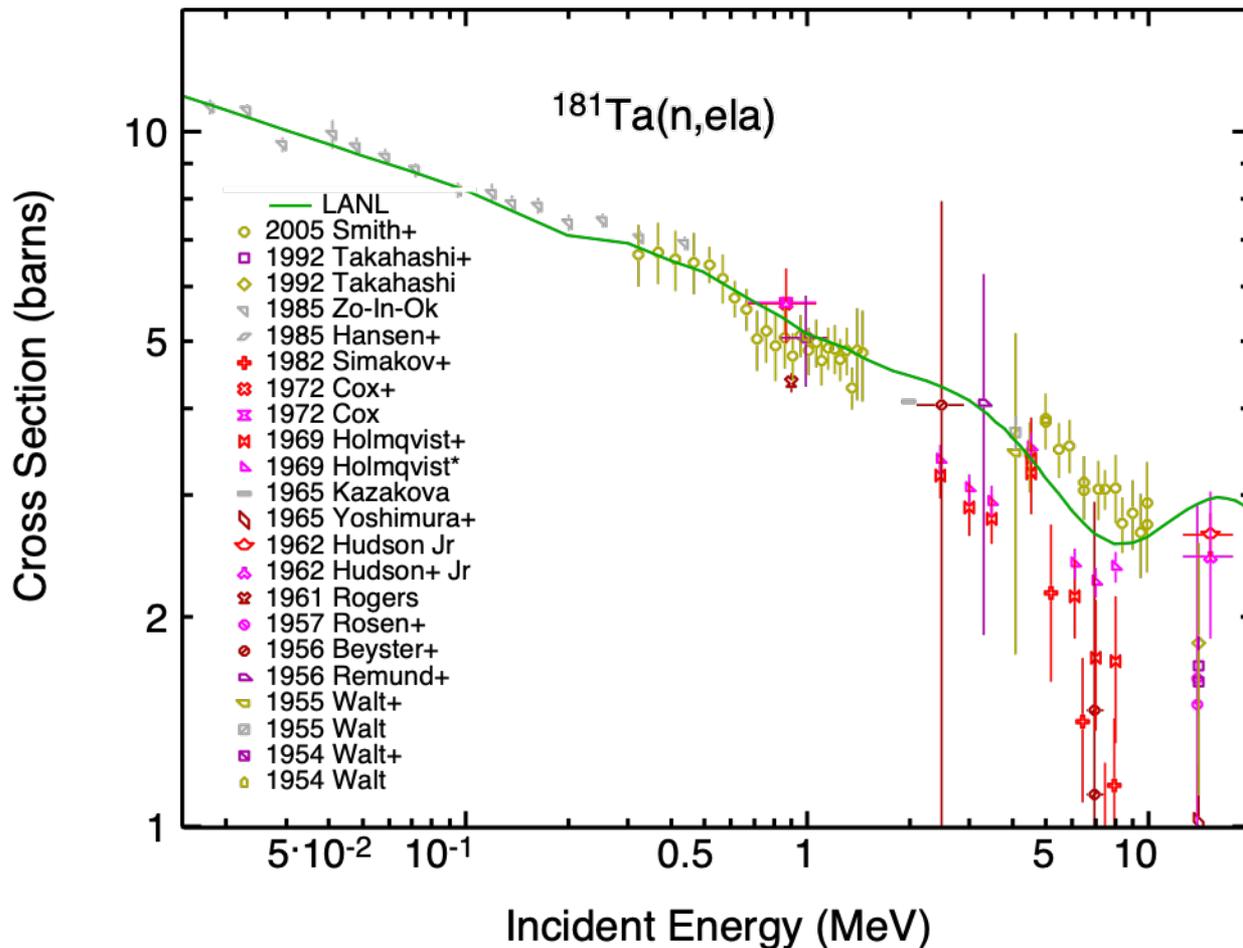

r_v	0.98542
V_v	1.0184
a_v	1.0870
β_2	1.0444
β_4	0.93707
β_6	0.49351

Five experiments that support the evaluated total compared with the CC calculations using updated optical potential.

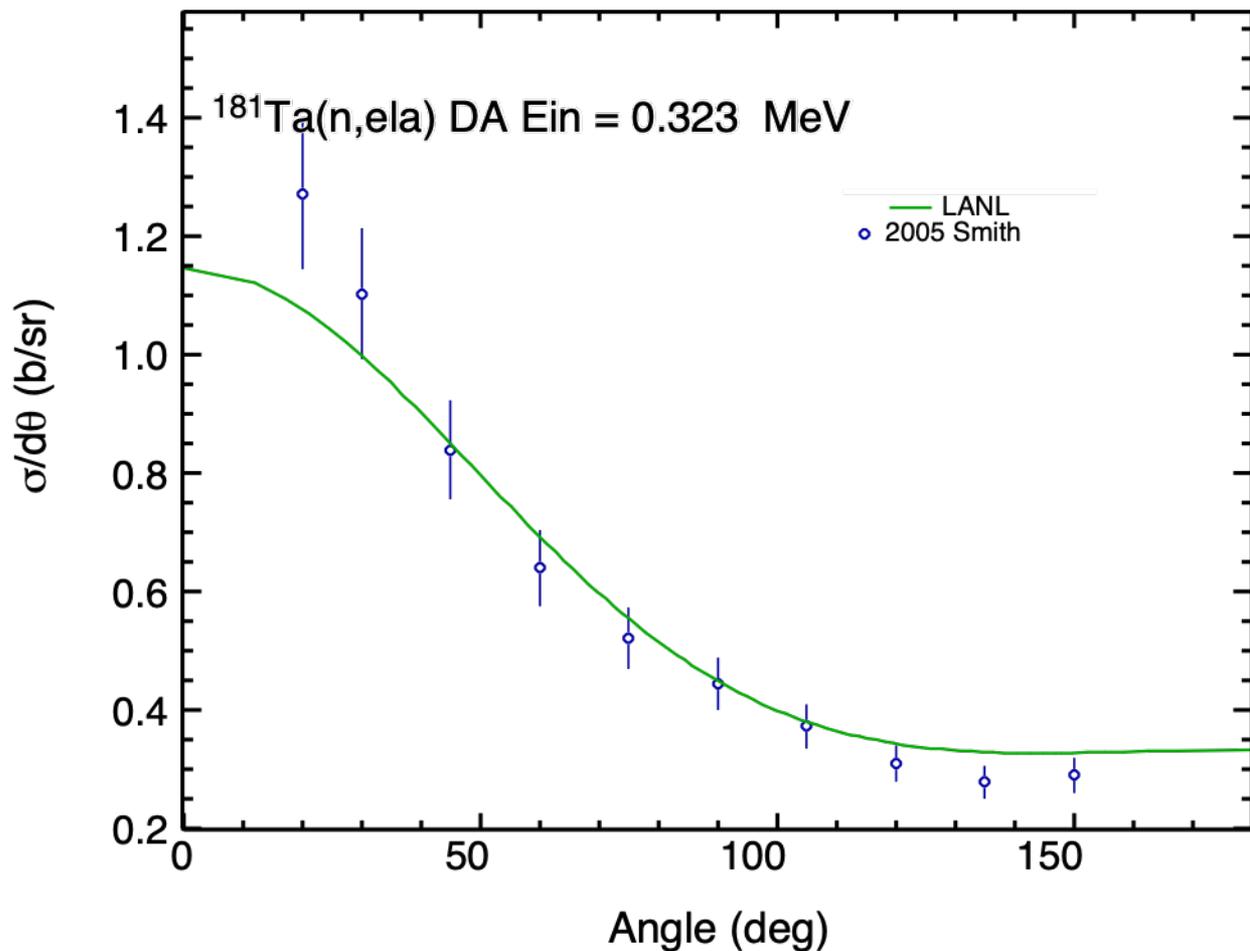

LANL evaluation perfectly fits Rapp, Poenitz 81 & 83, Tsubone, Smith, and Carlson.

CC model - elastic x-sec & angular distributions

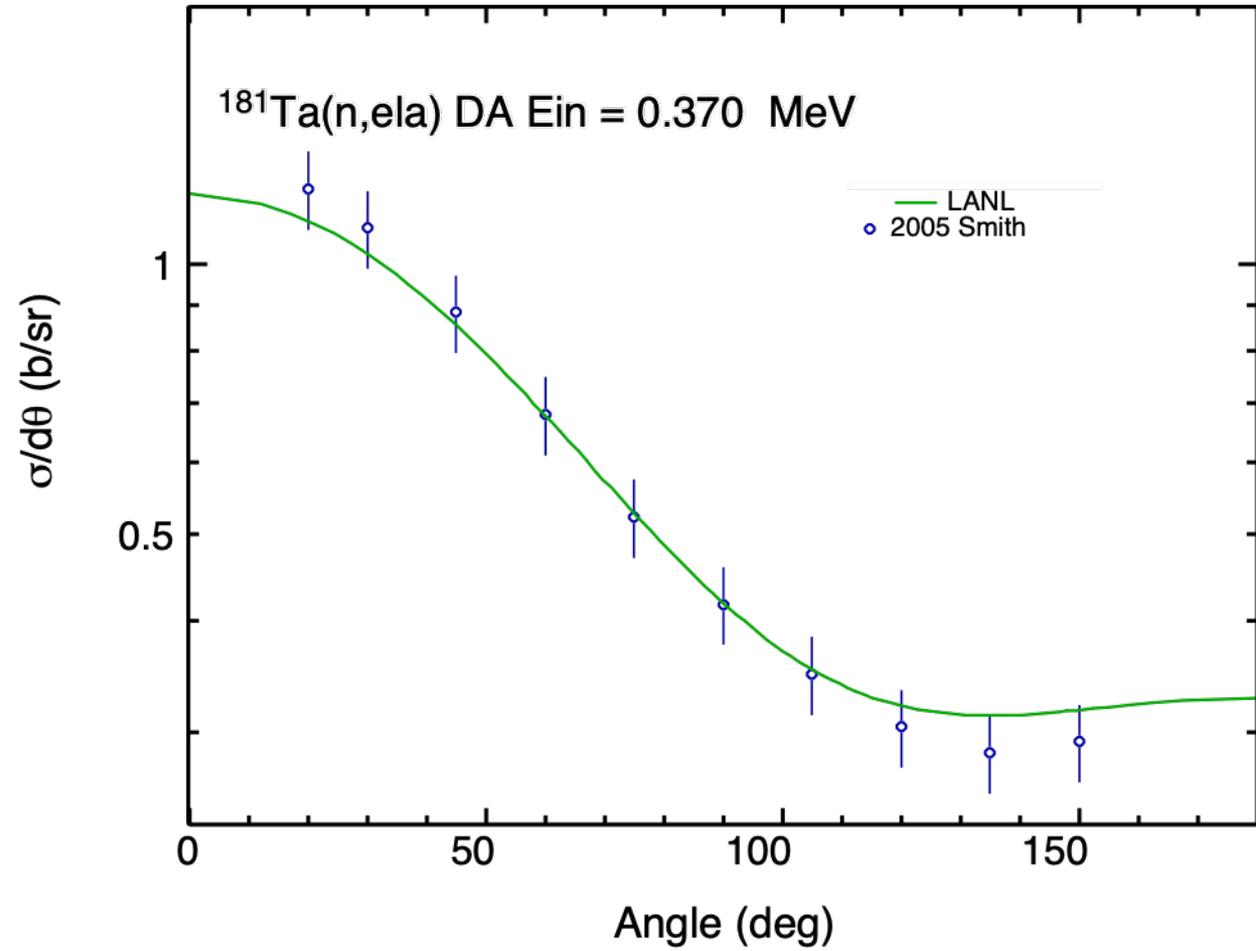

Elastic cross sections after adding the 1-st and the 2-nd inelastic.

Elastic angular distributions A. Smith: 0.3 - 1.5 MeV

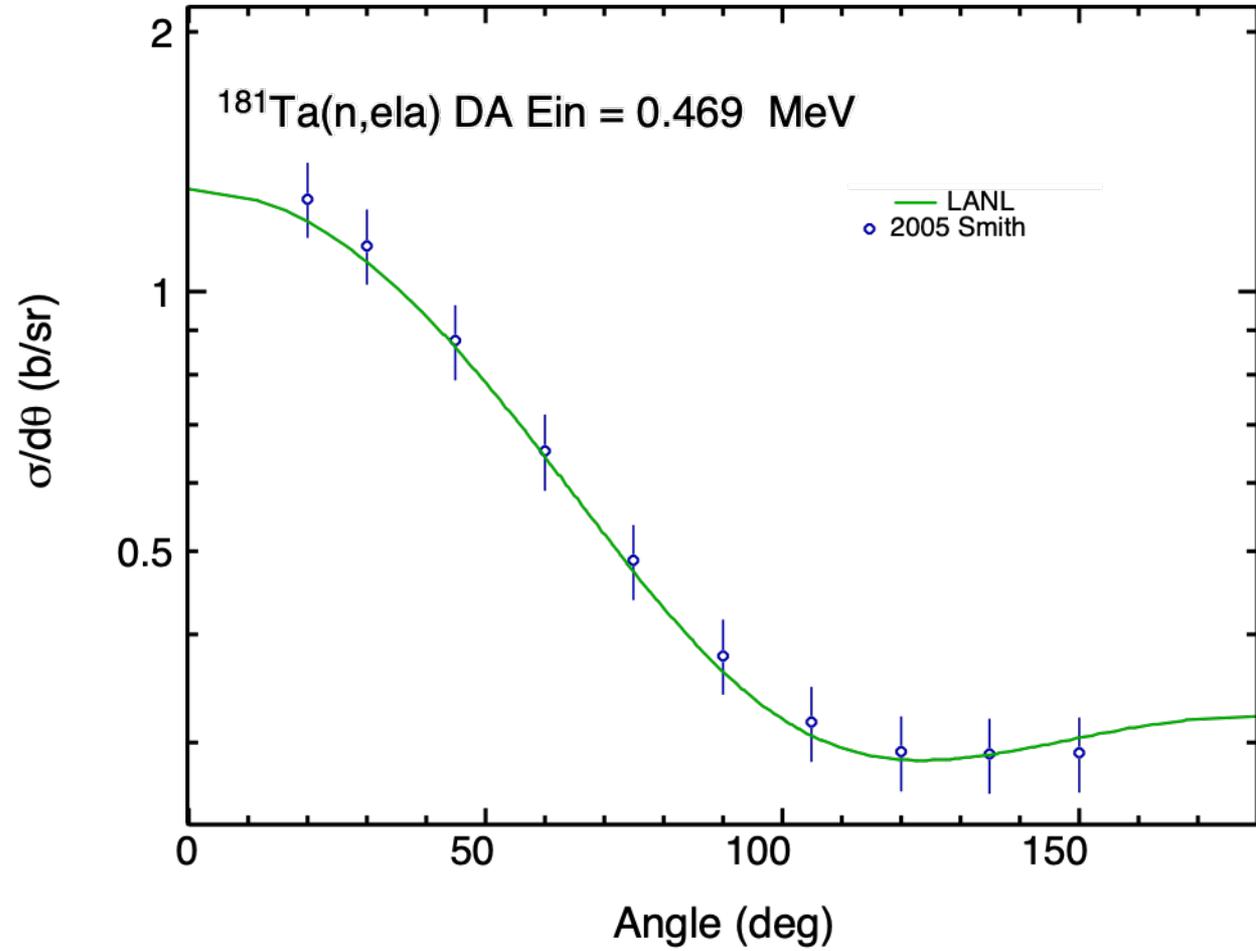

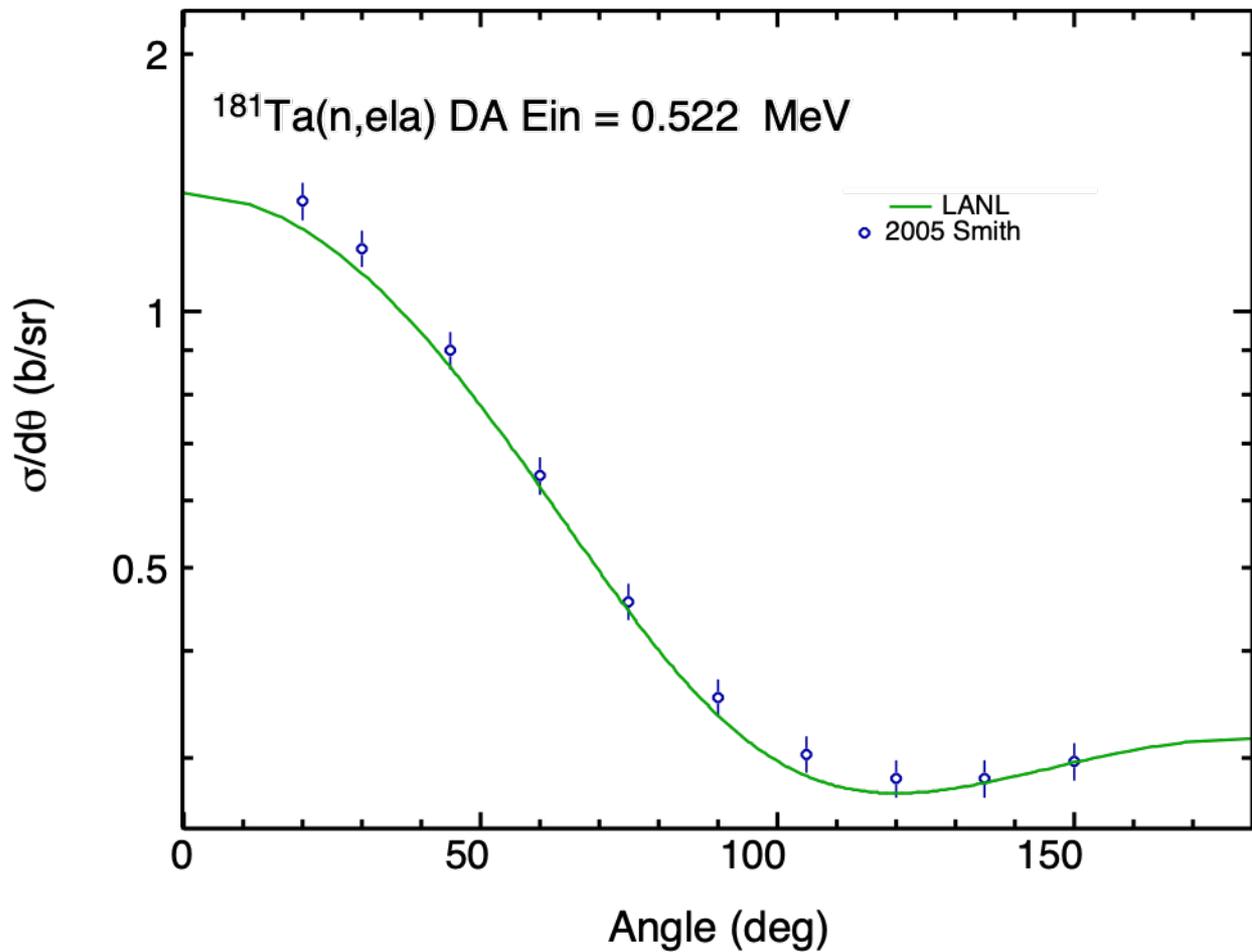

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.370$ MeV

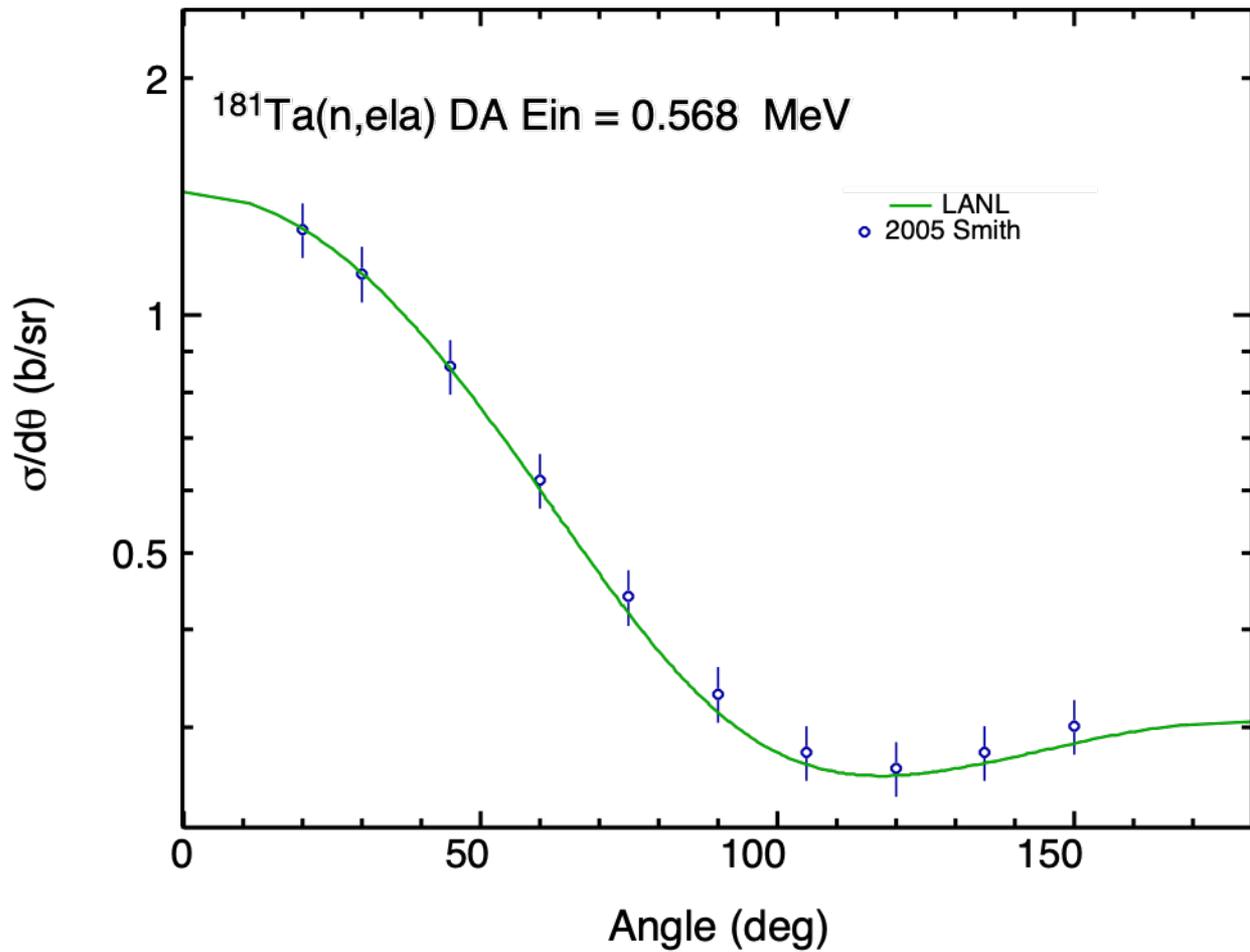

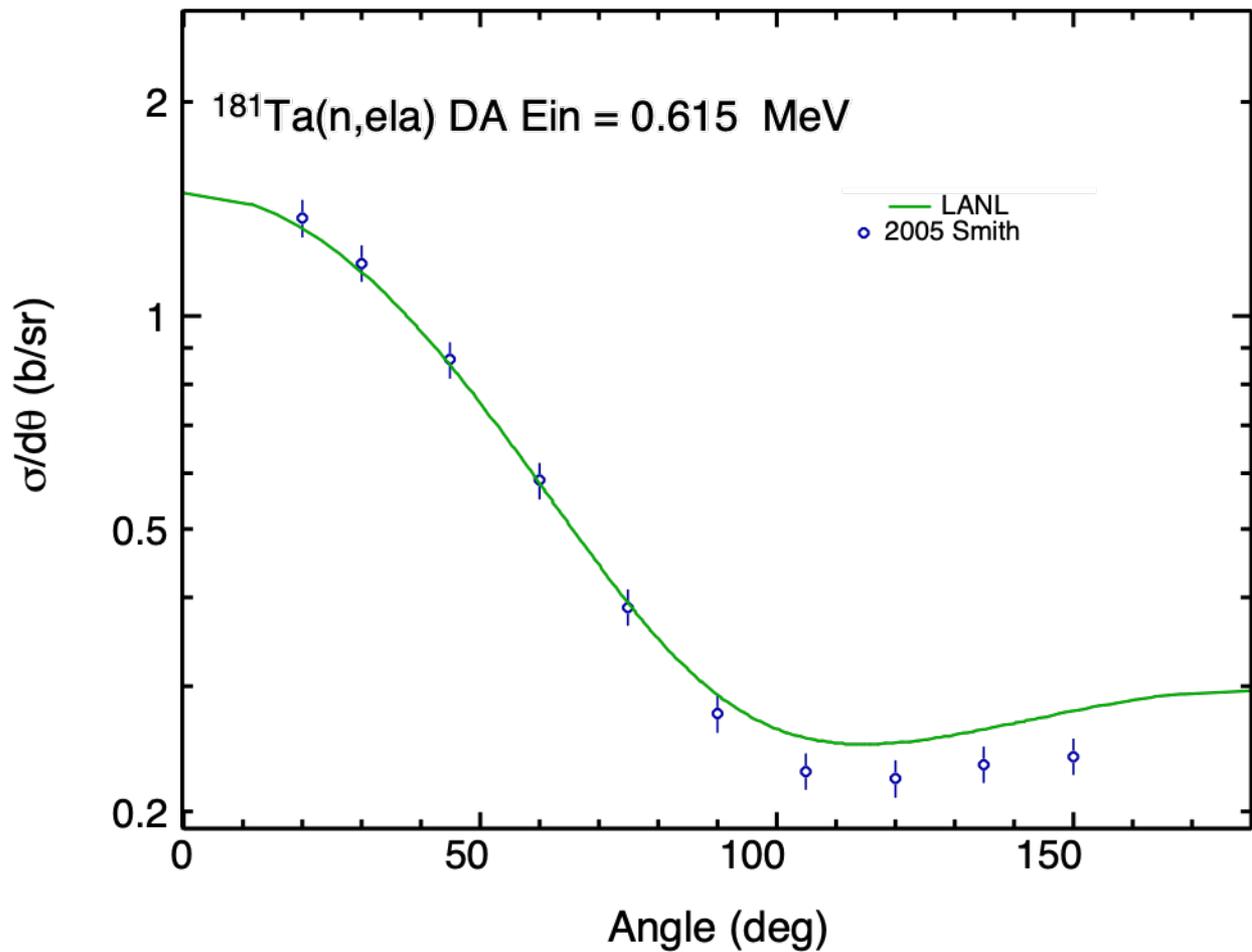

The 1-st and the 2-nd inelastic angular distributions added.

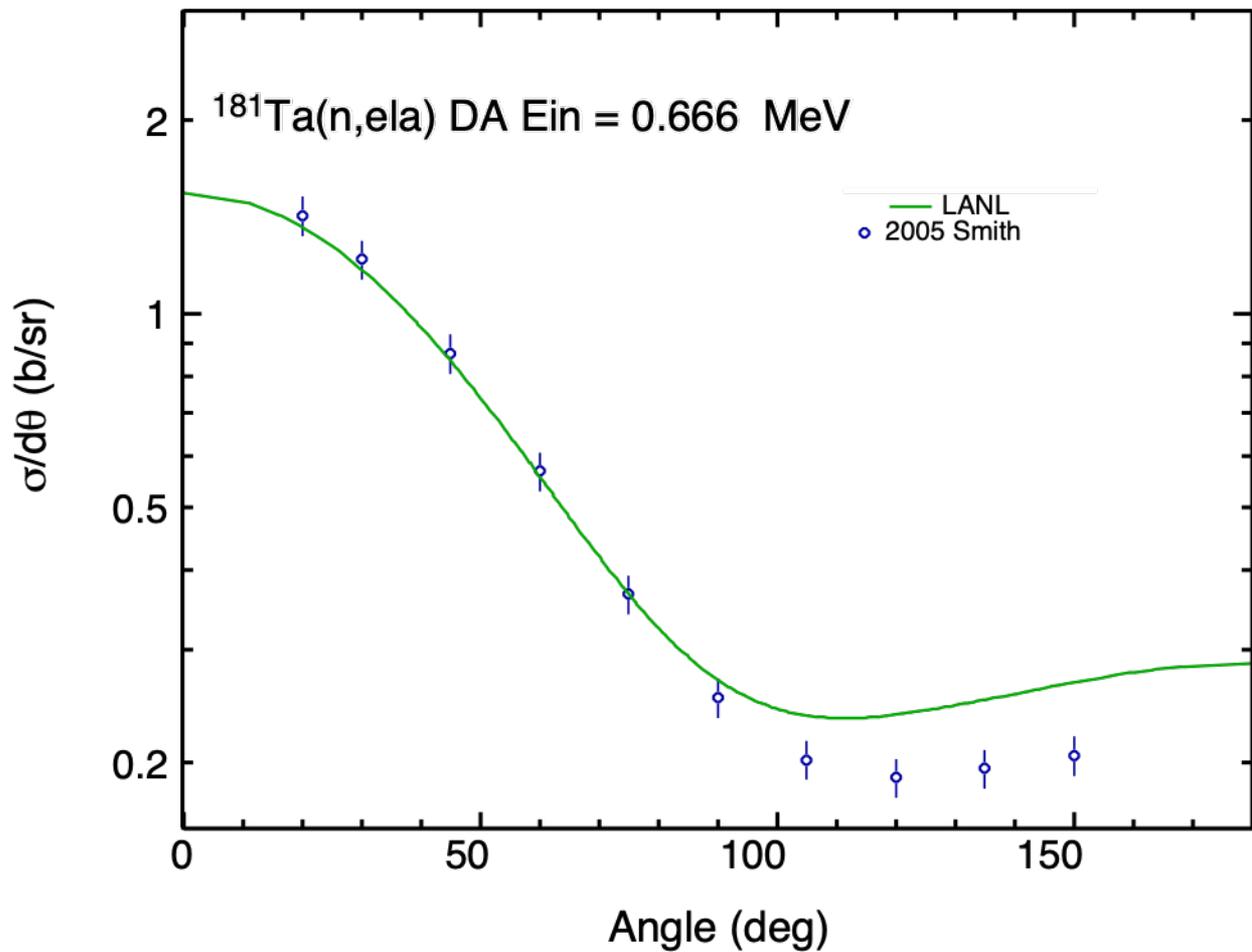

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.469$ MeV

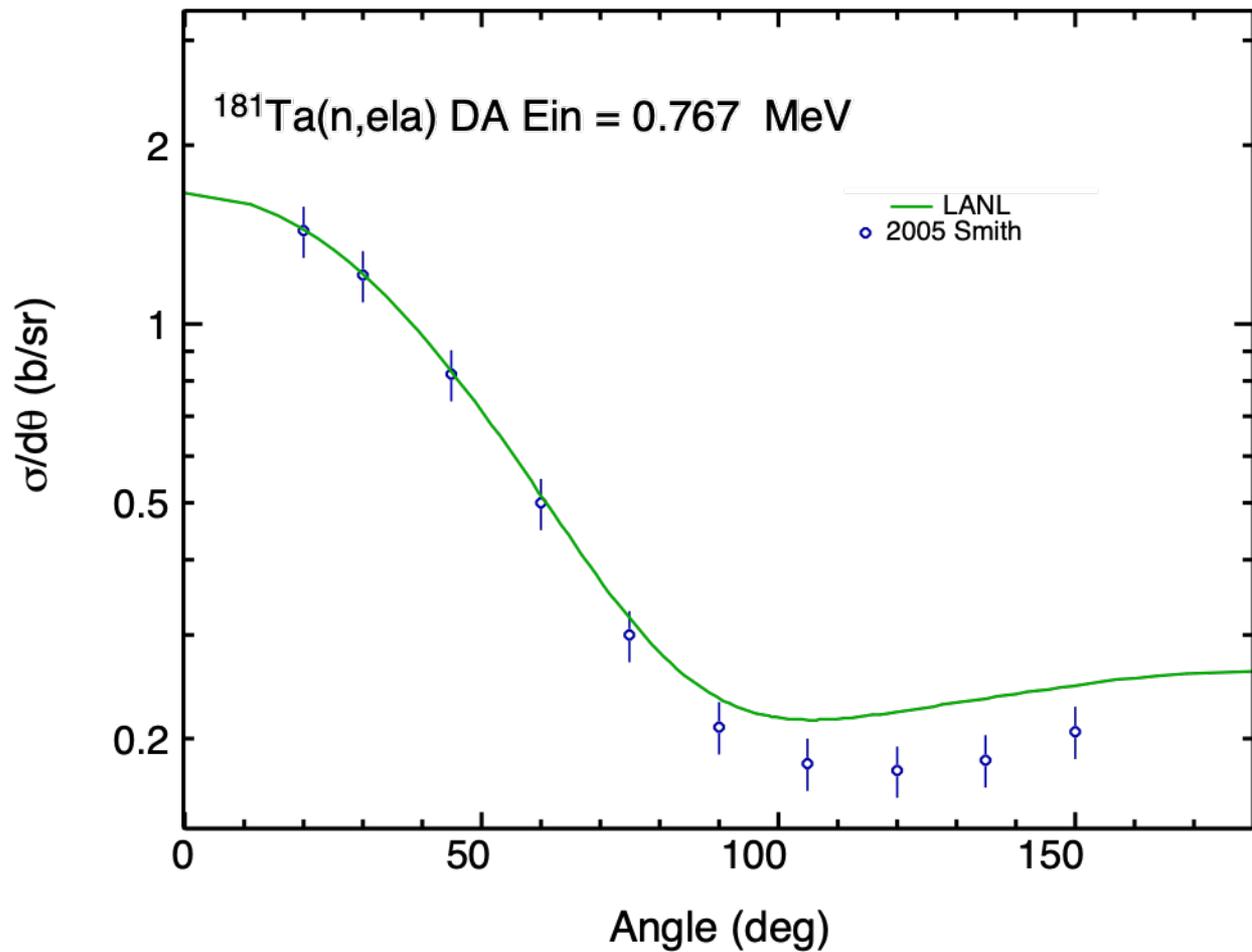

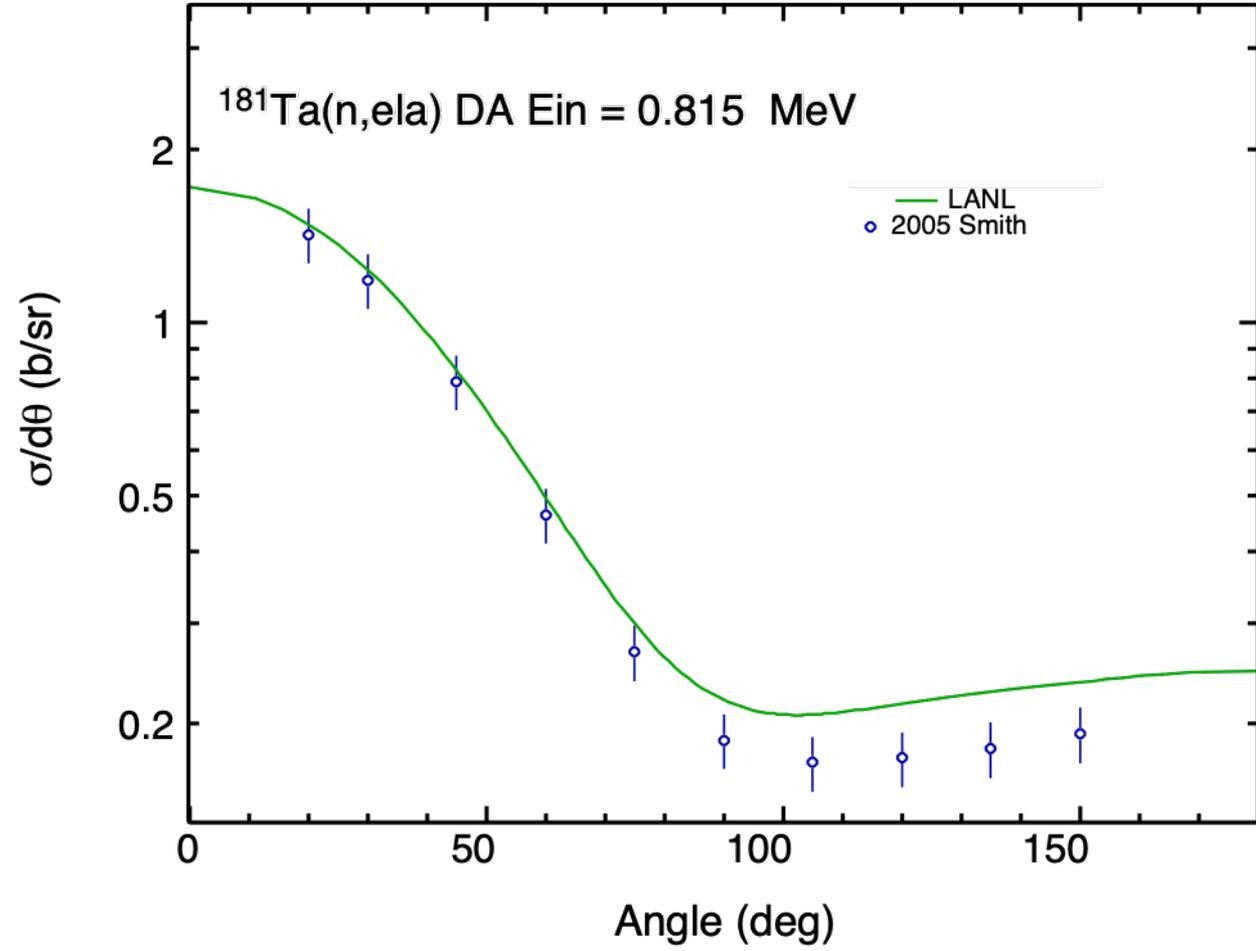

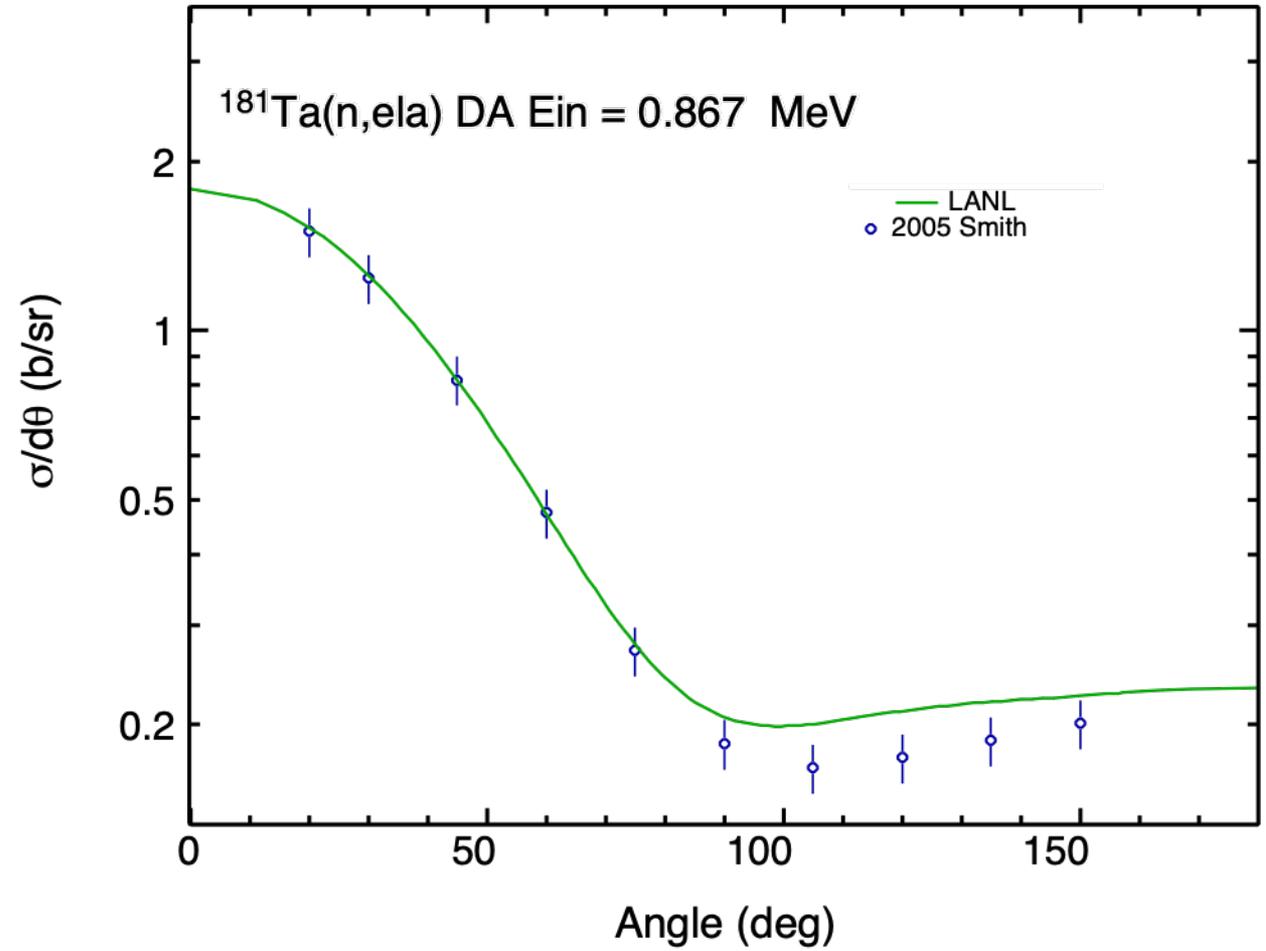

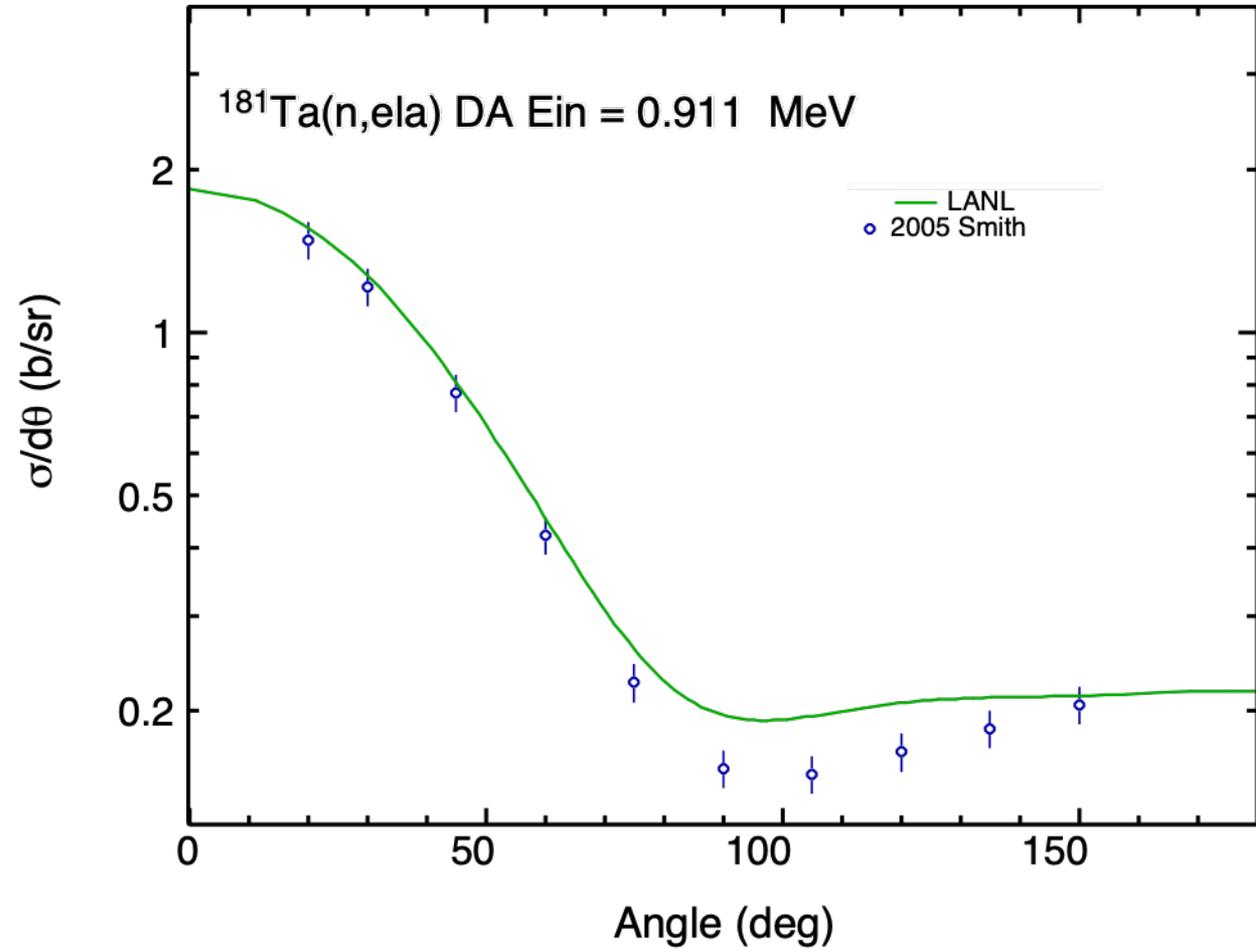

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.815$ MeV

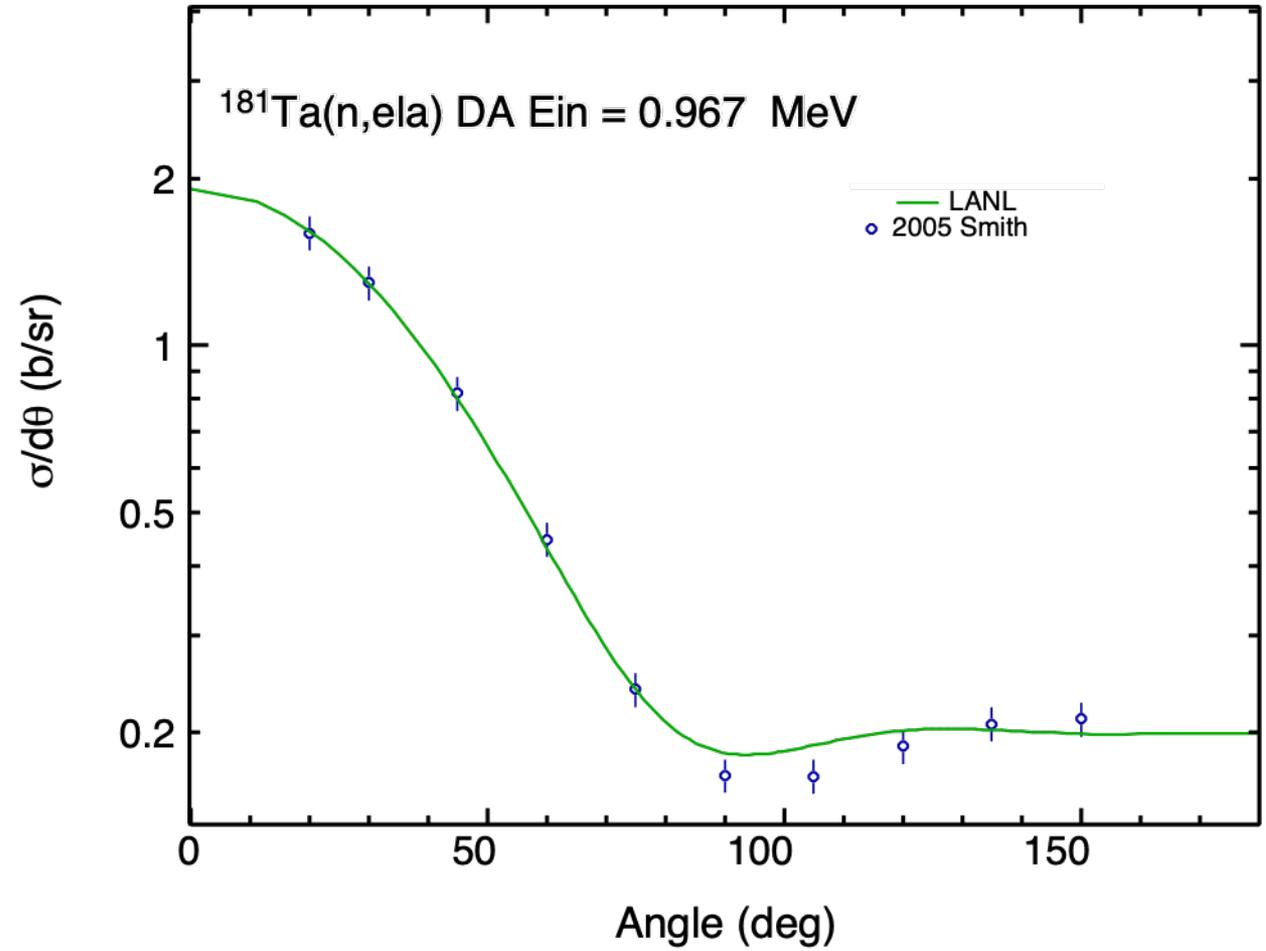

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.867$ MeV

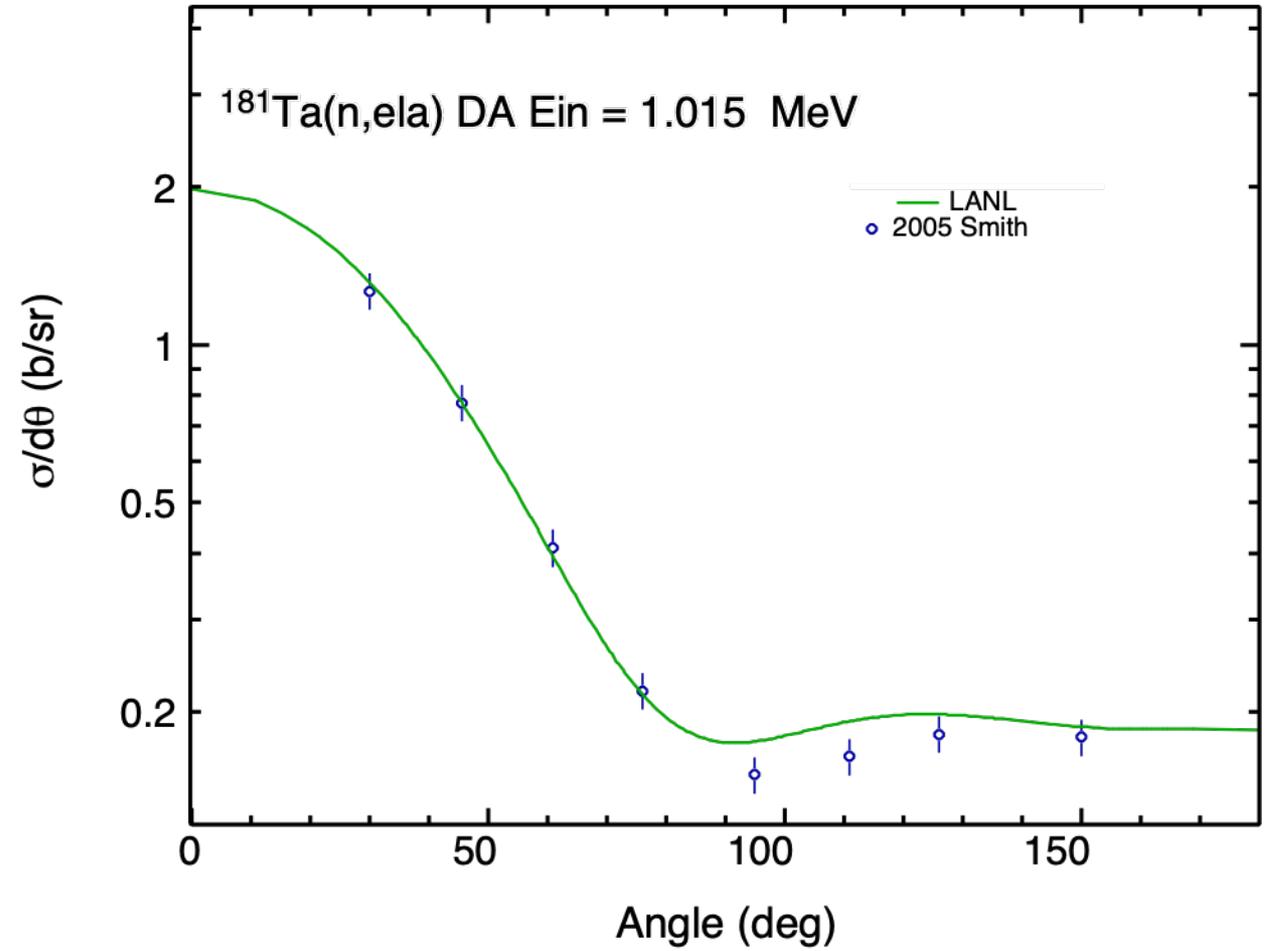

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.911$ MeV

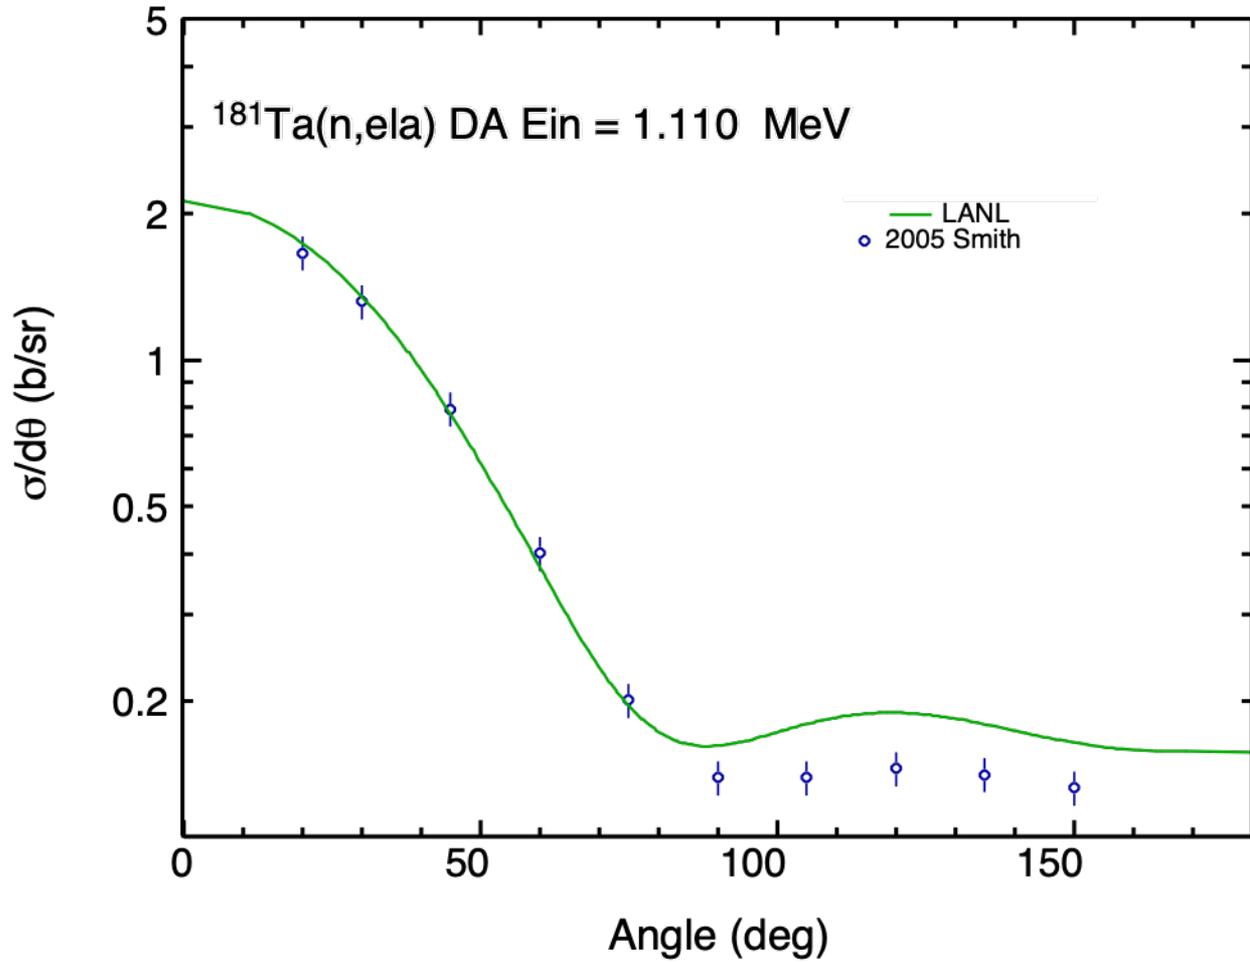

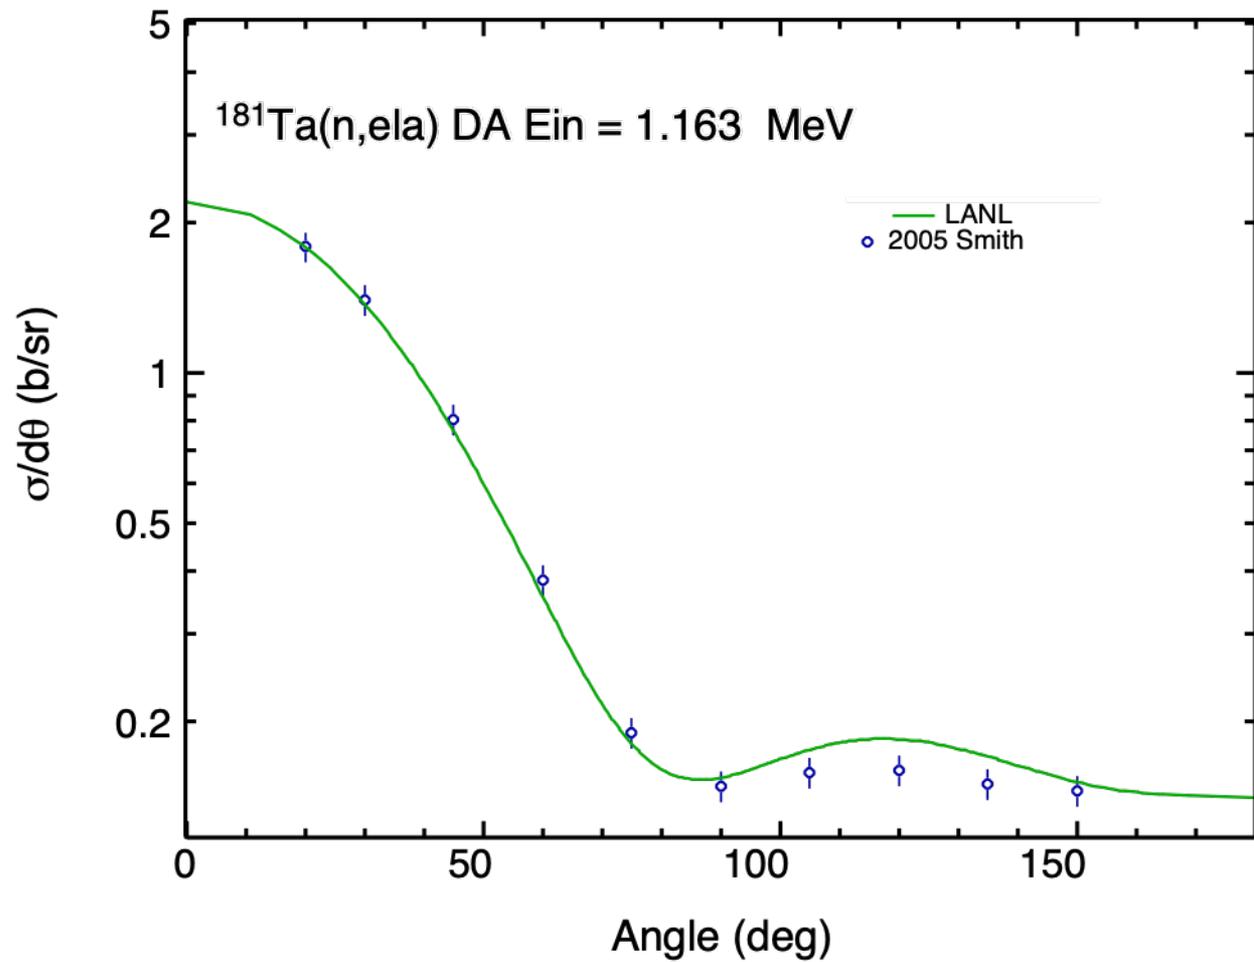

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 0.967$ MeV

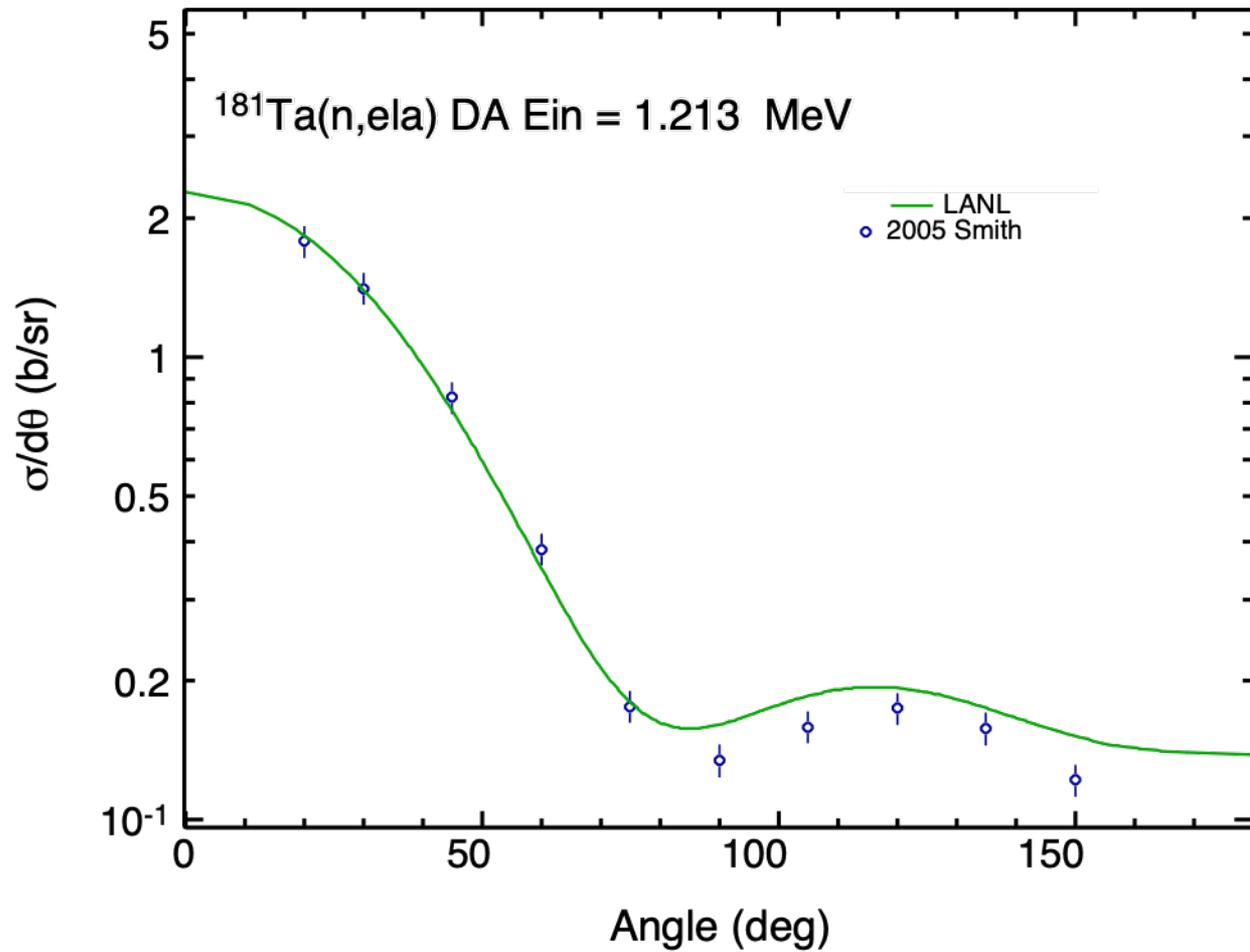

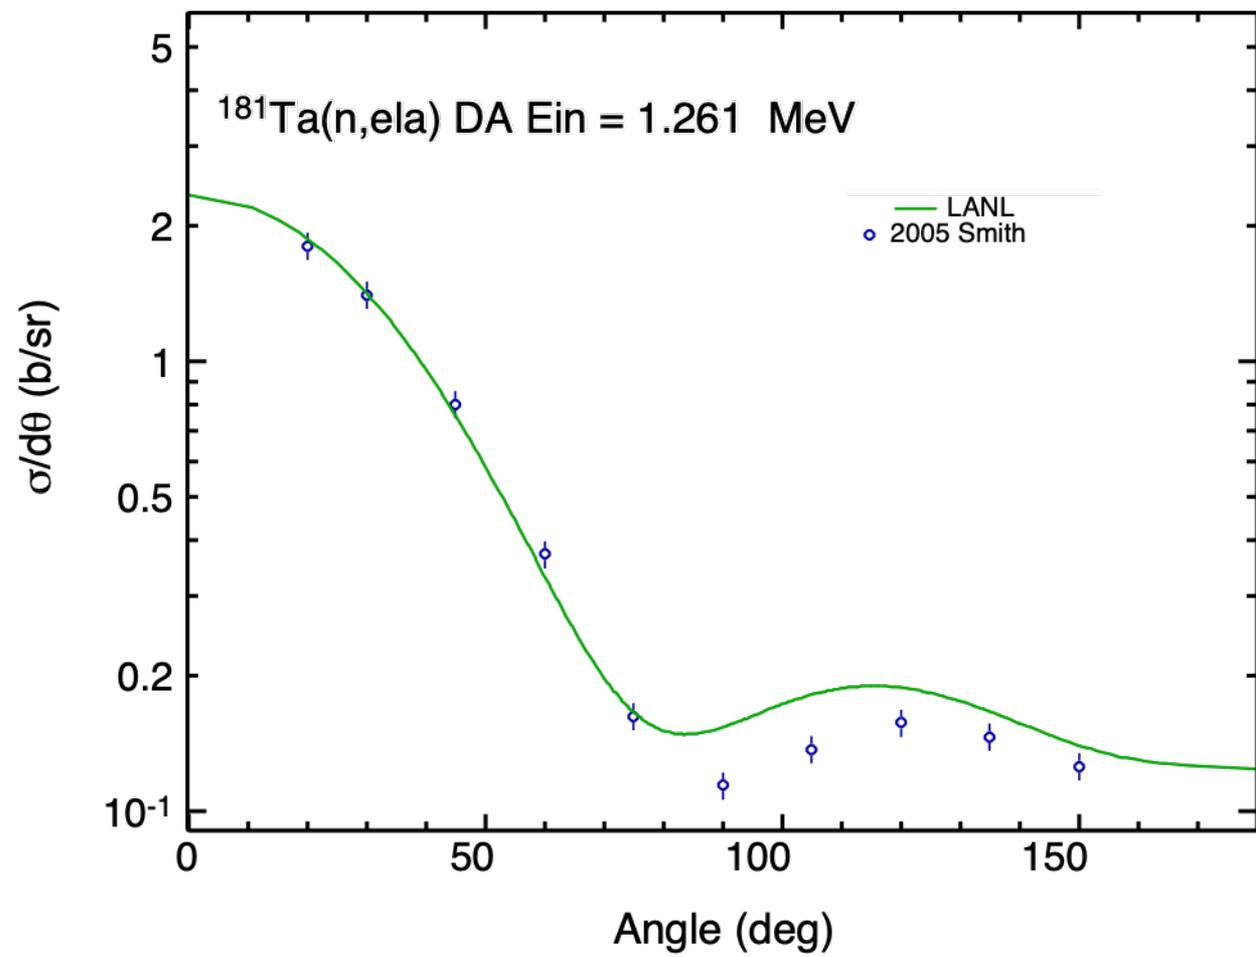

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 1.015 \text{ MeV}$

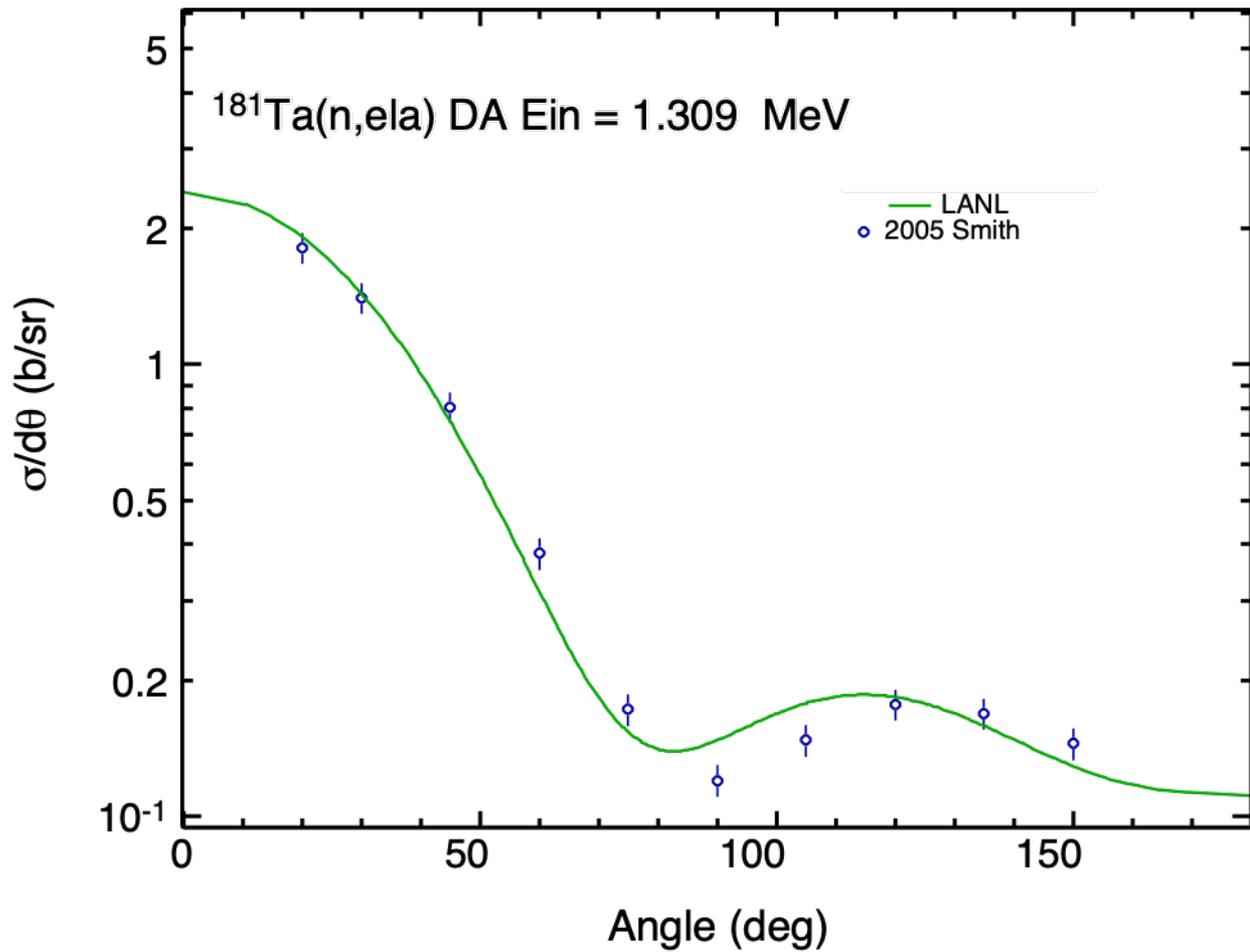

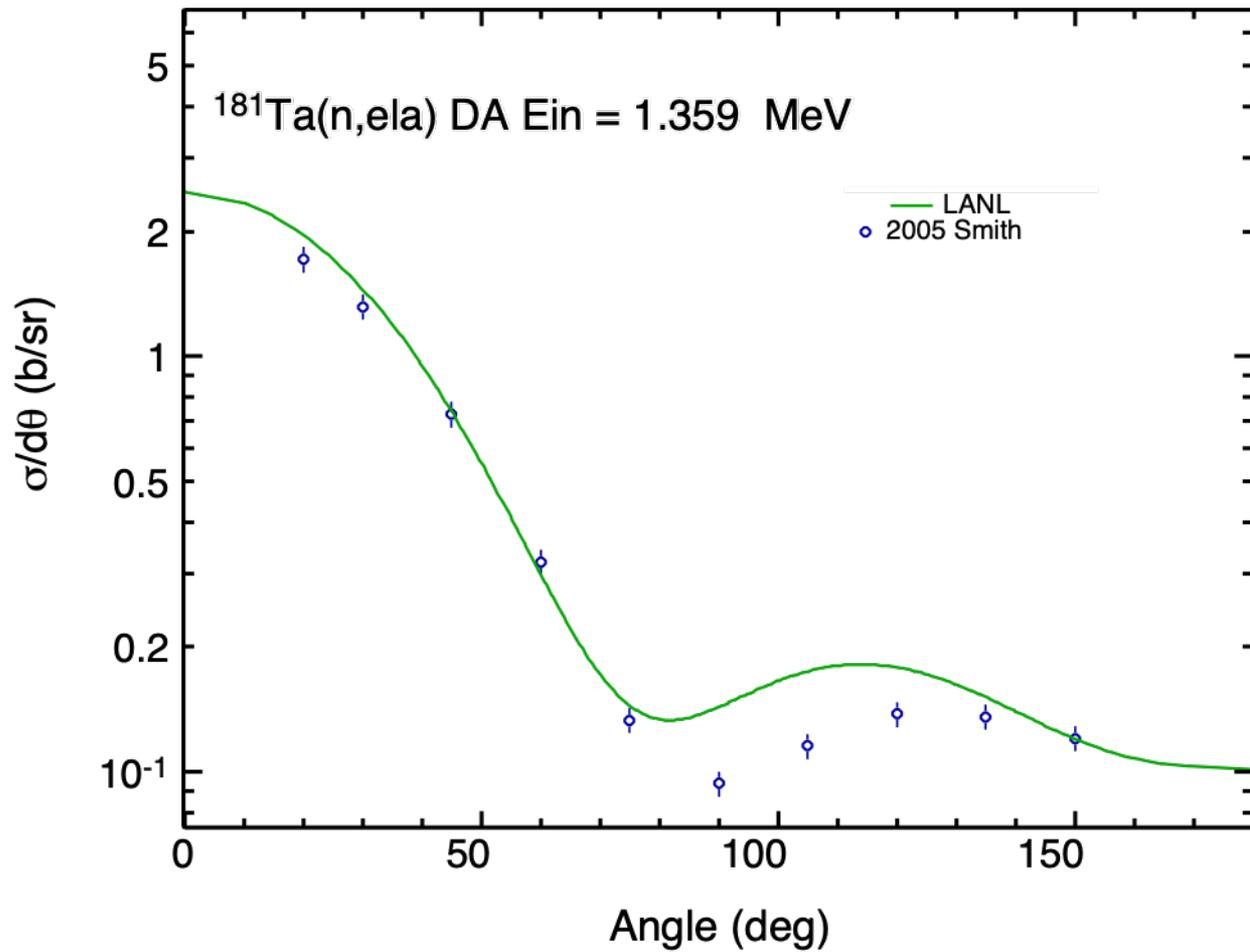

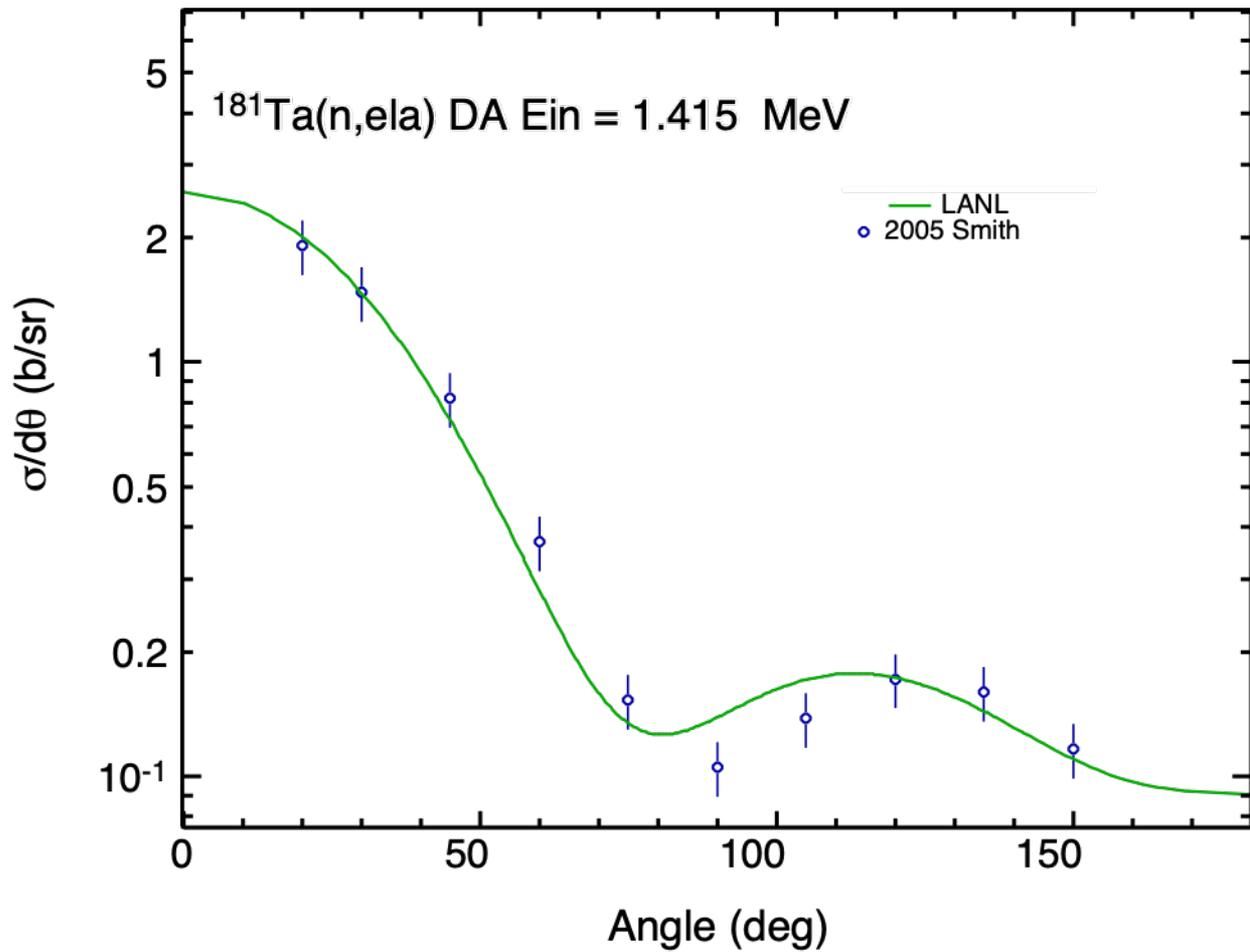

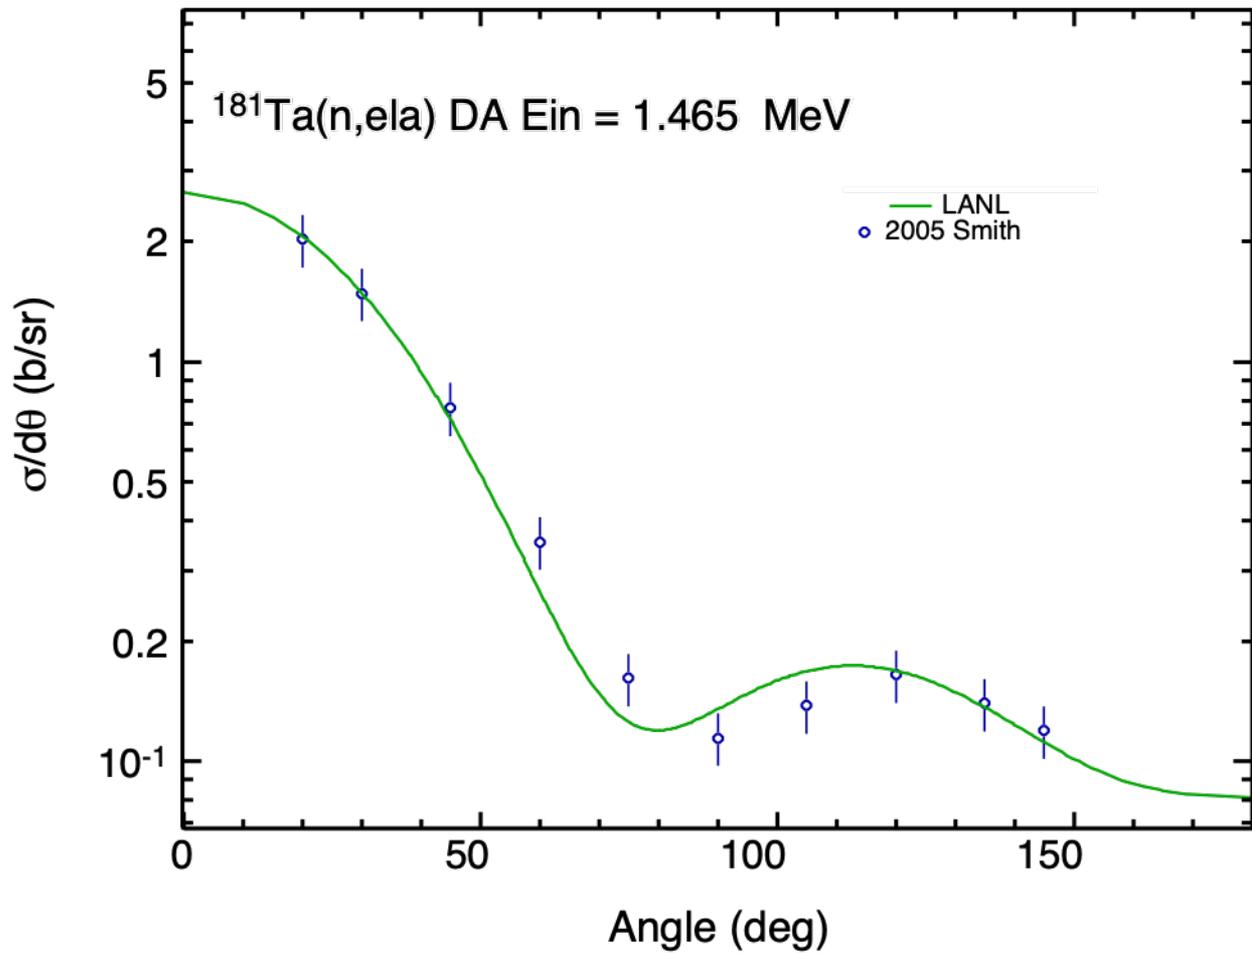

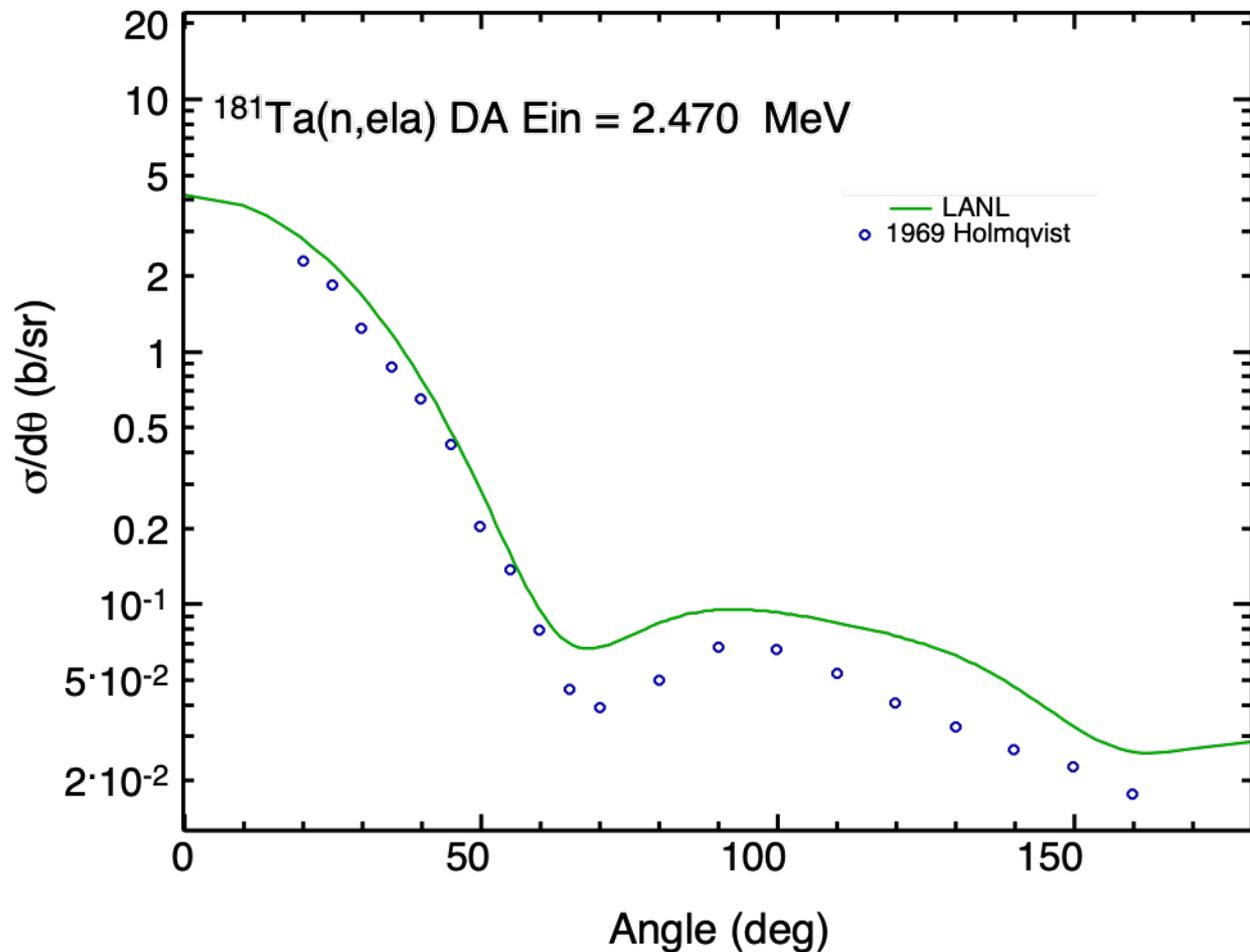

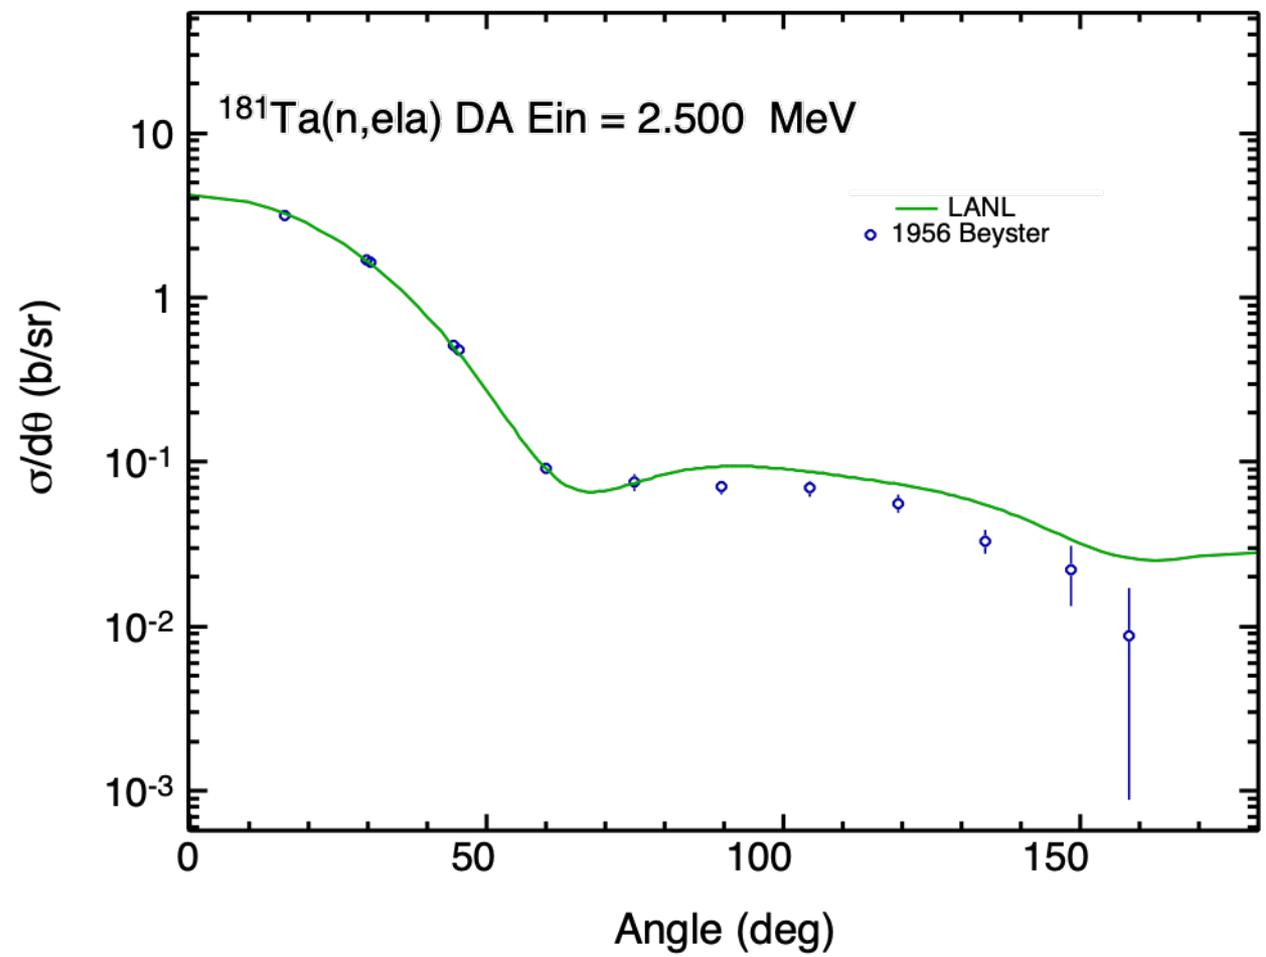

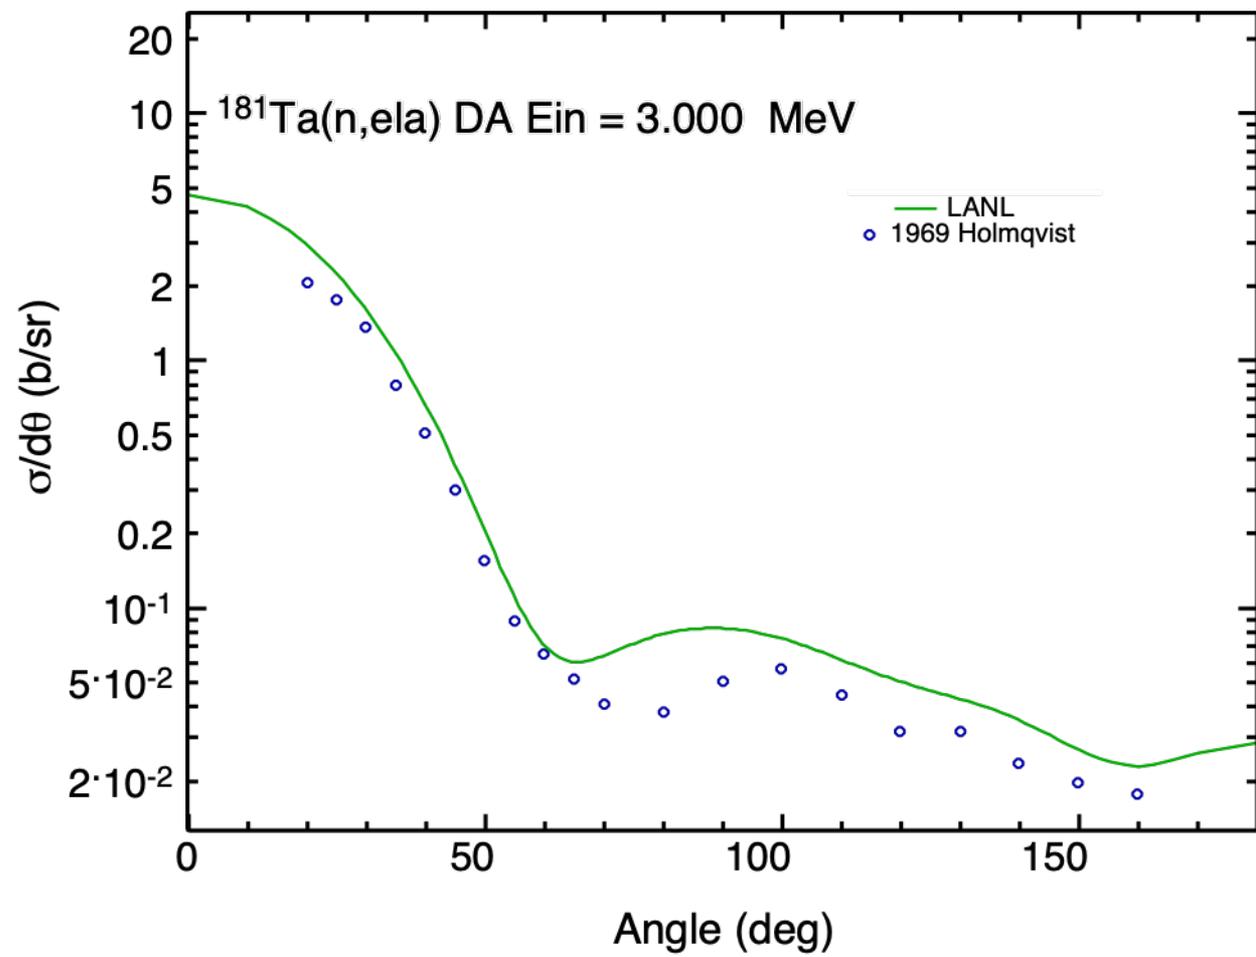

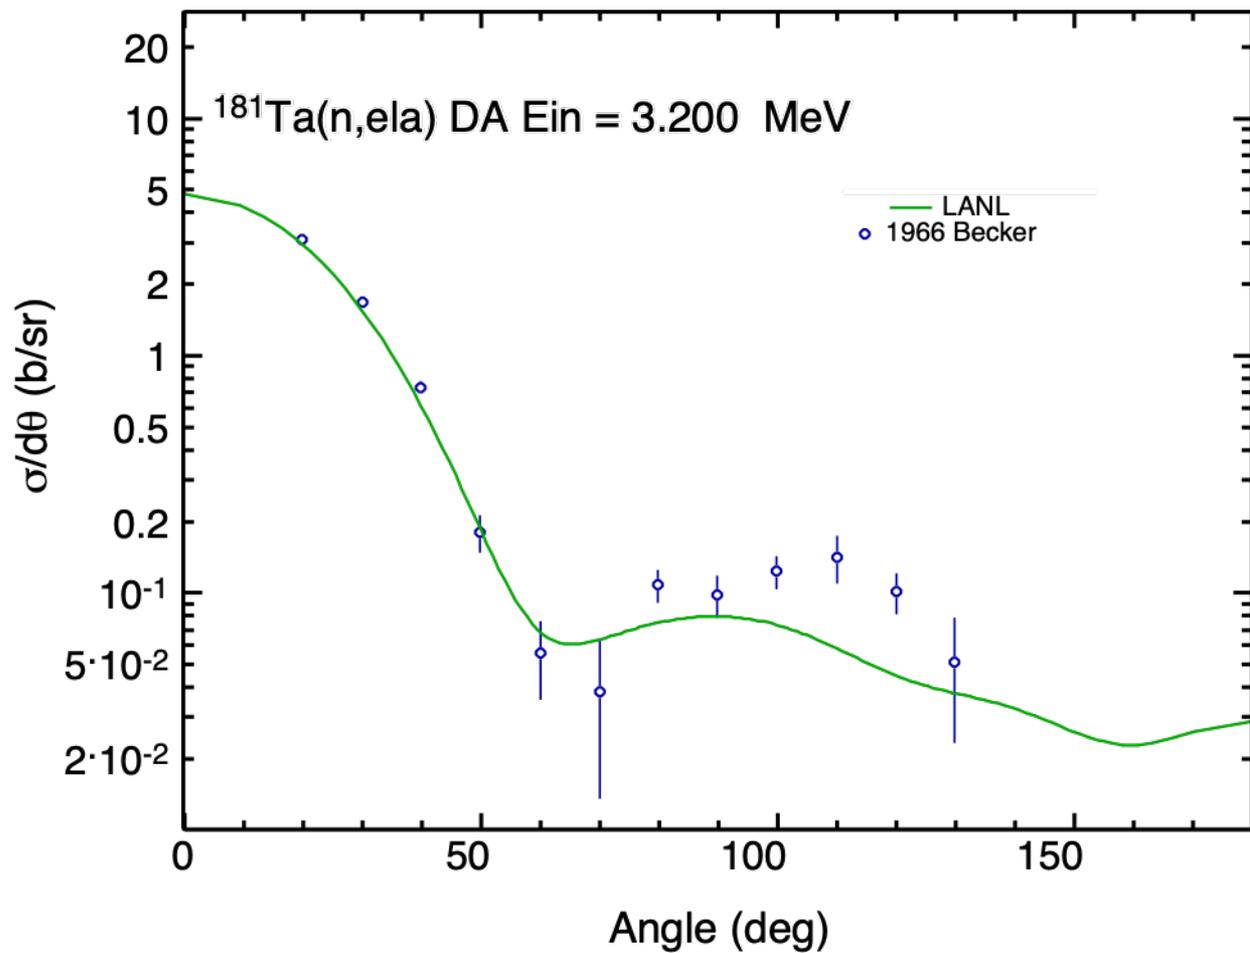

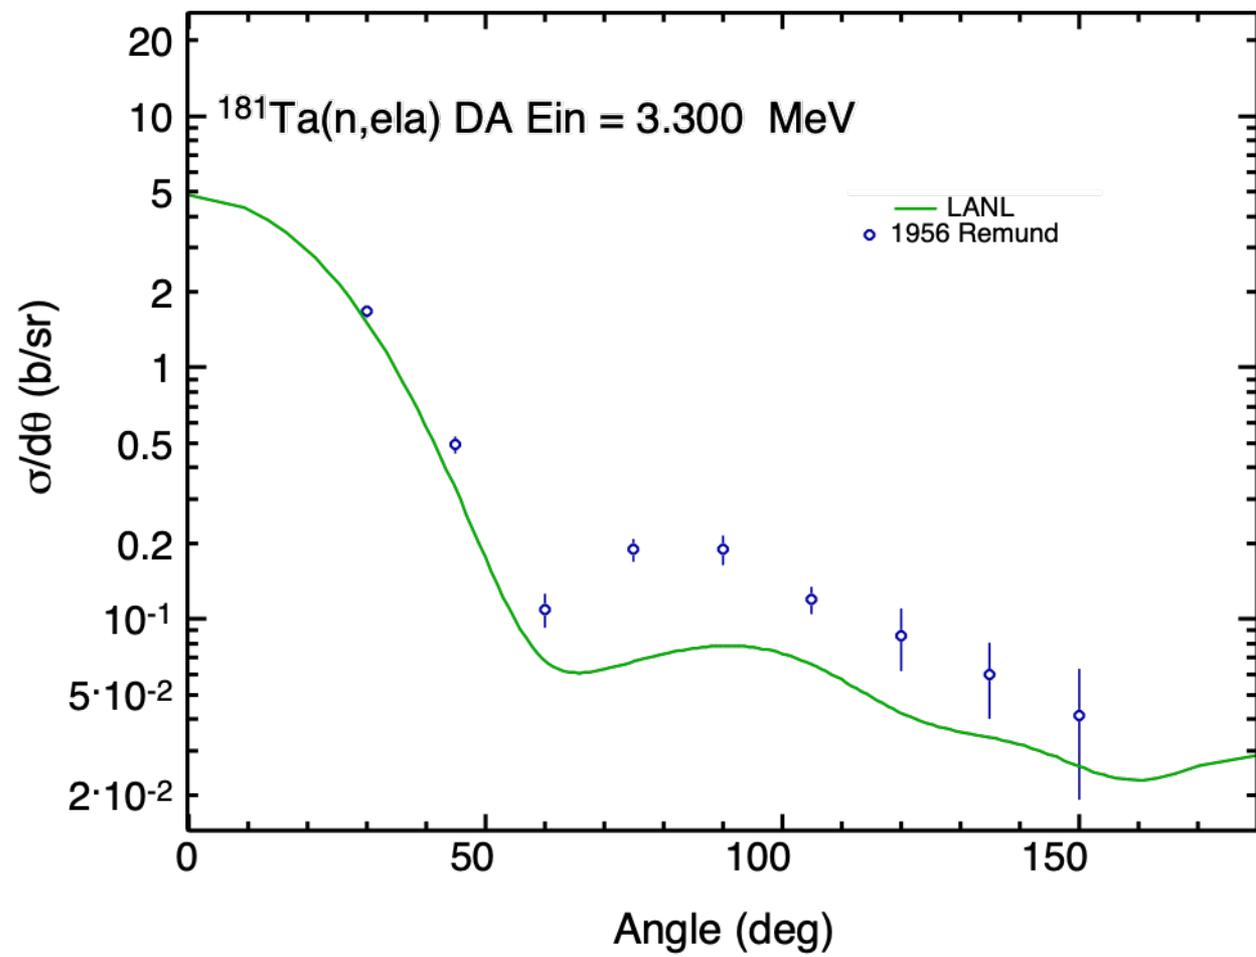

Various experiments: 2.5 - 15.2 MeV

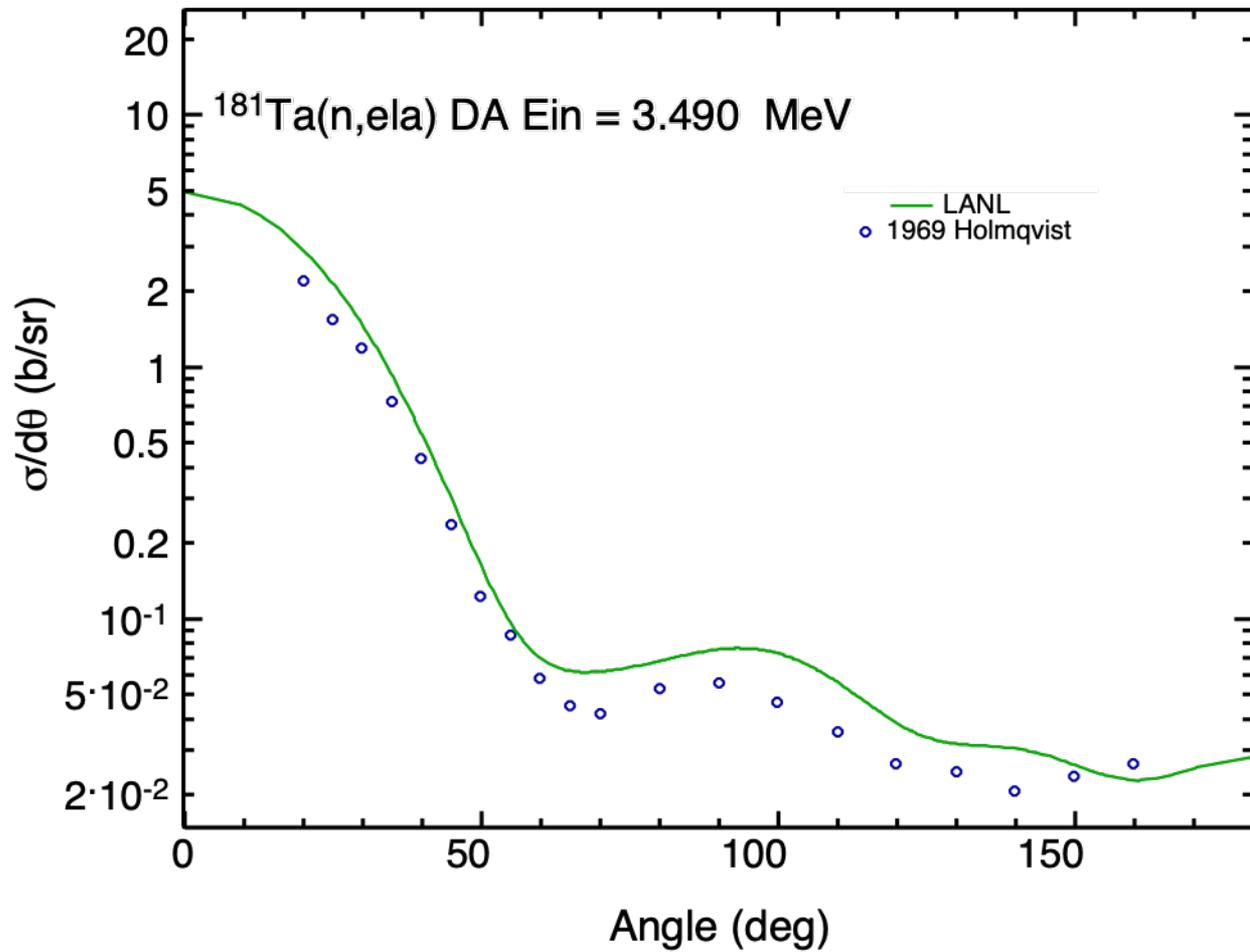

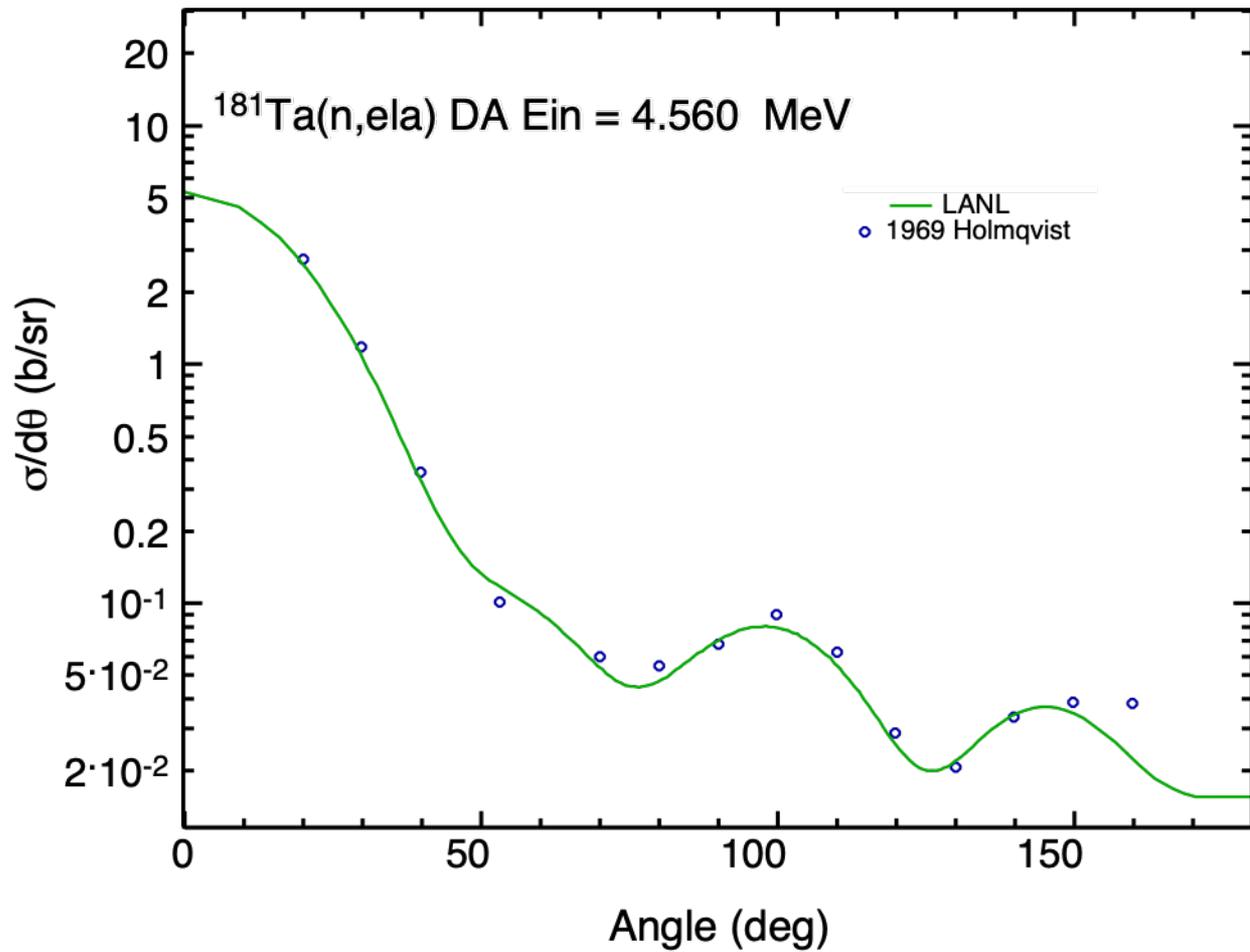

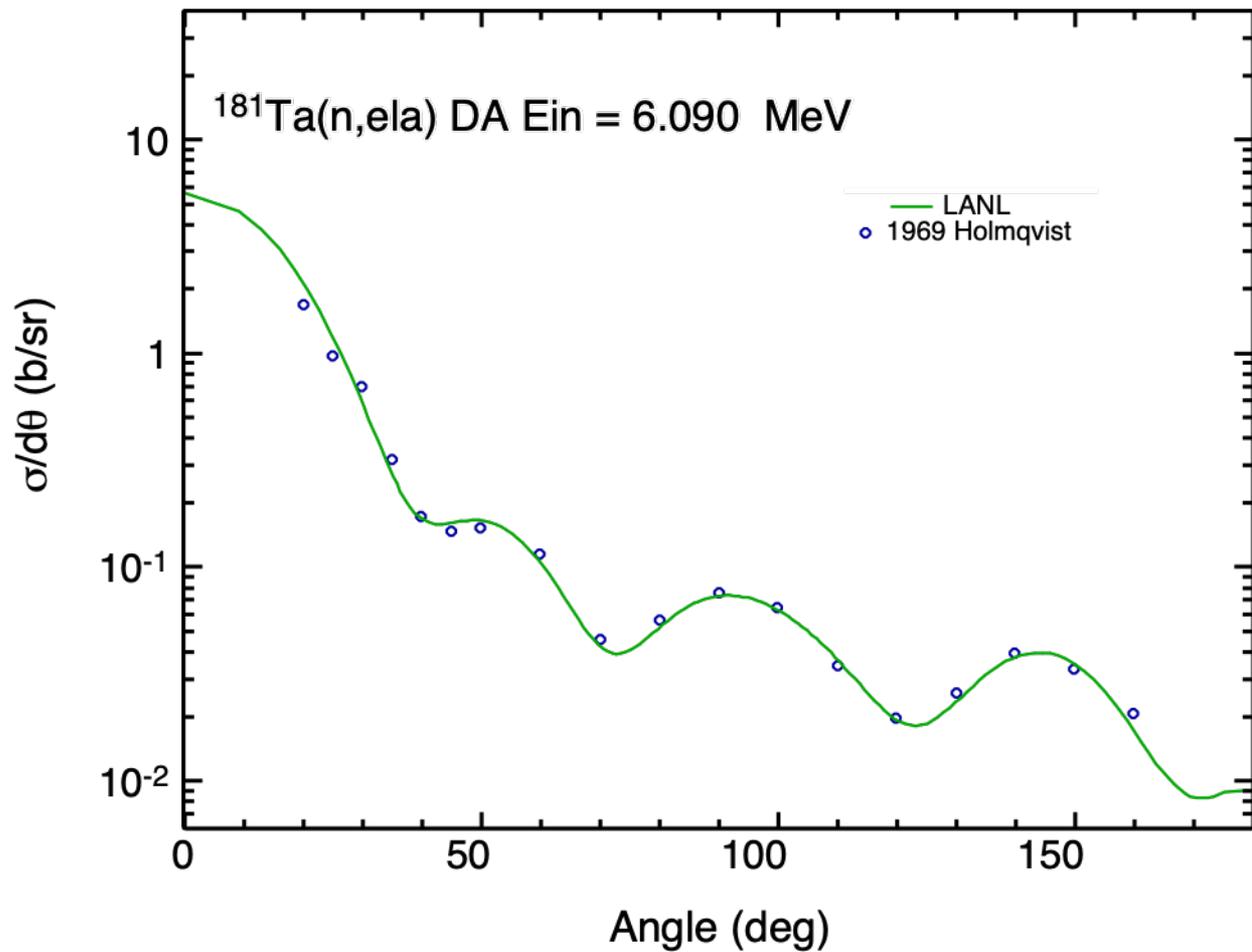

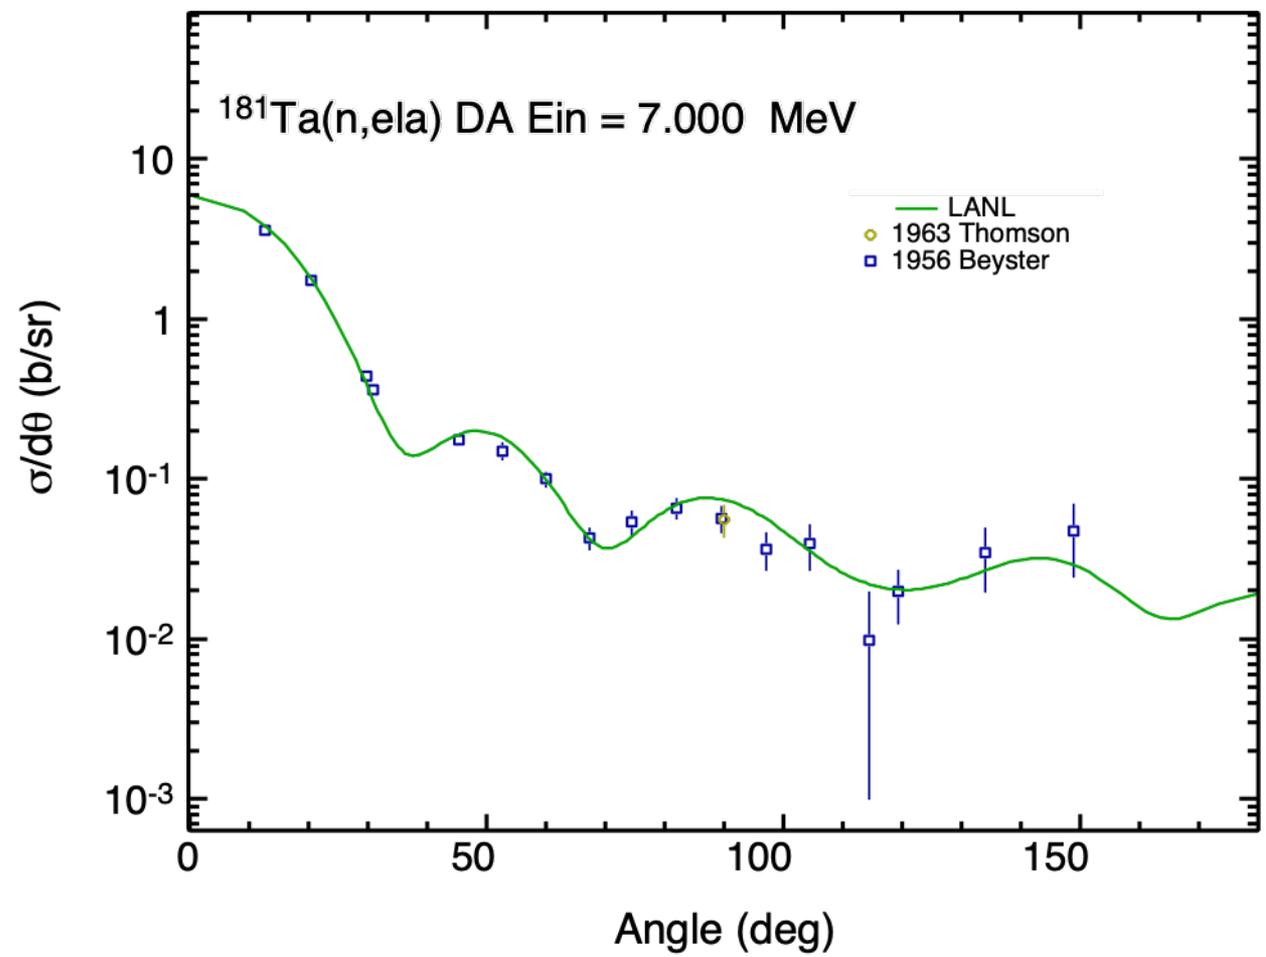

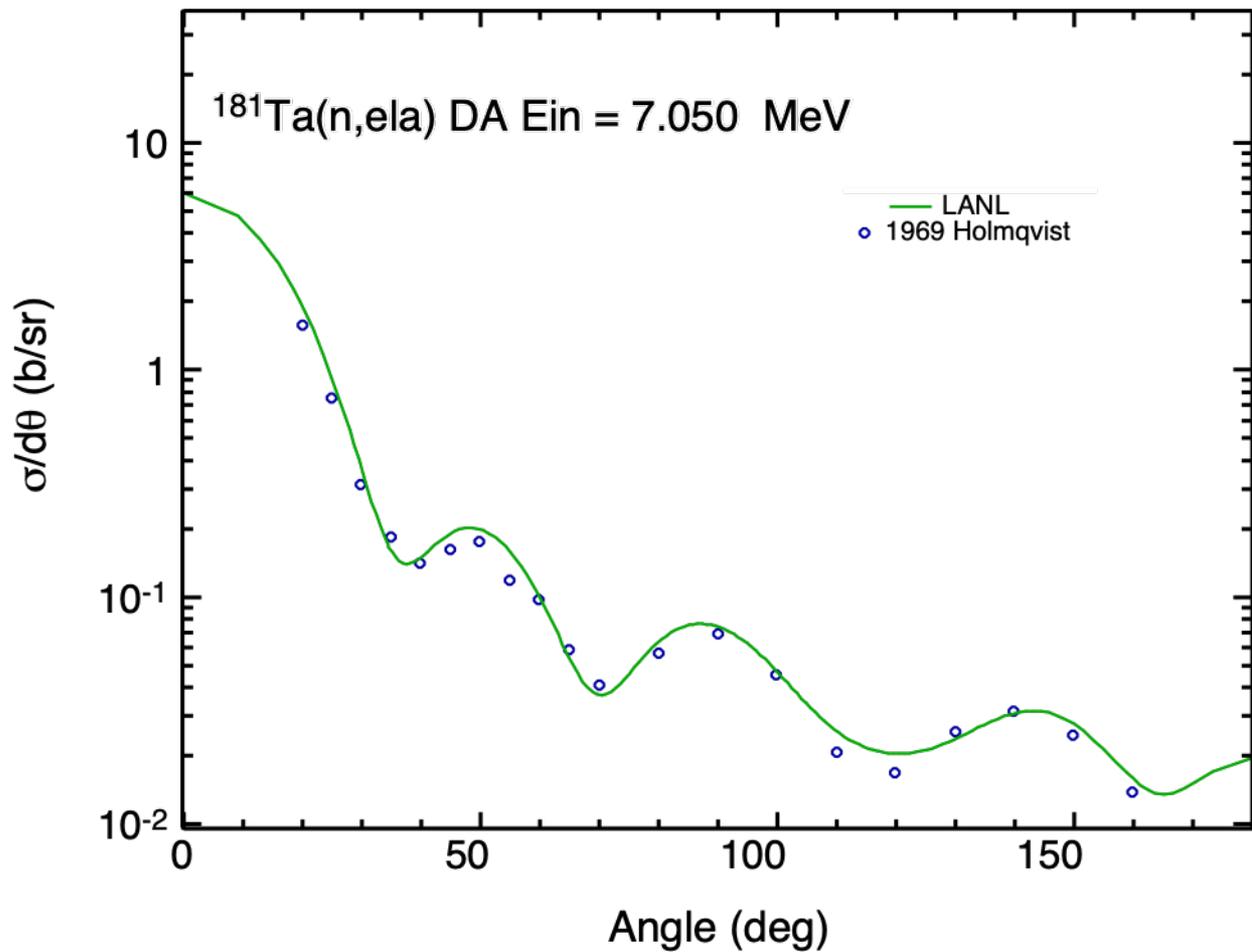

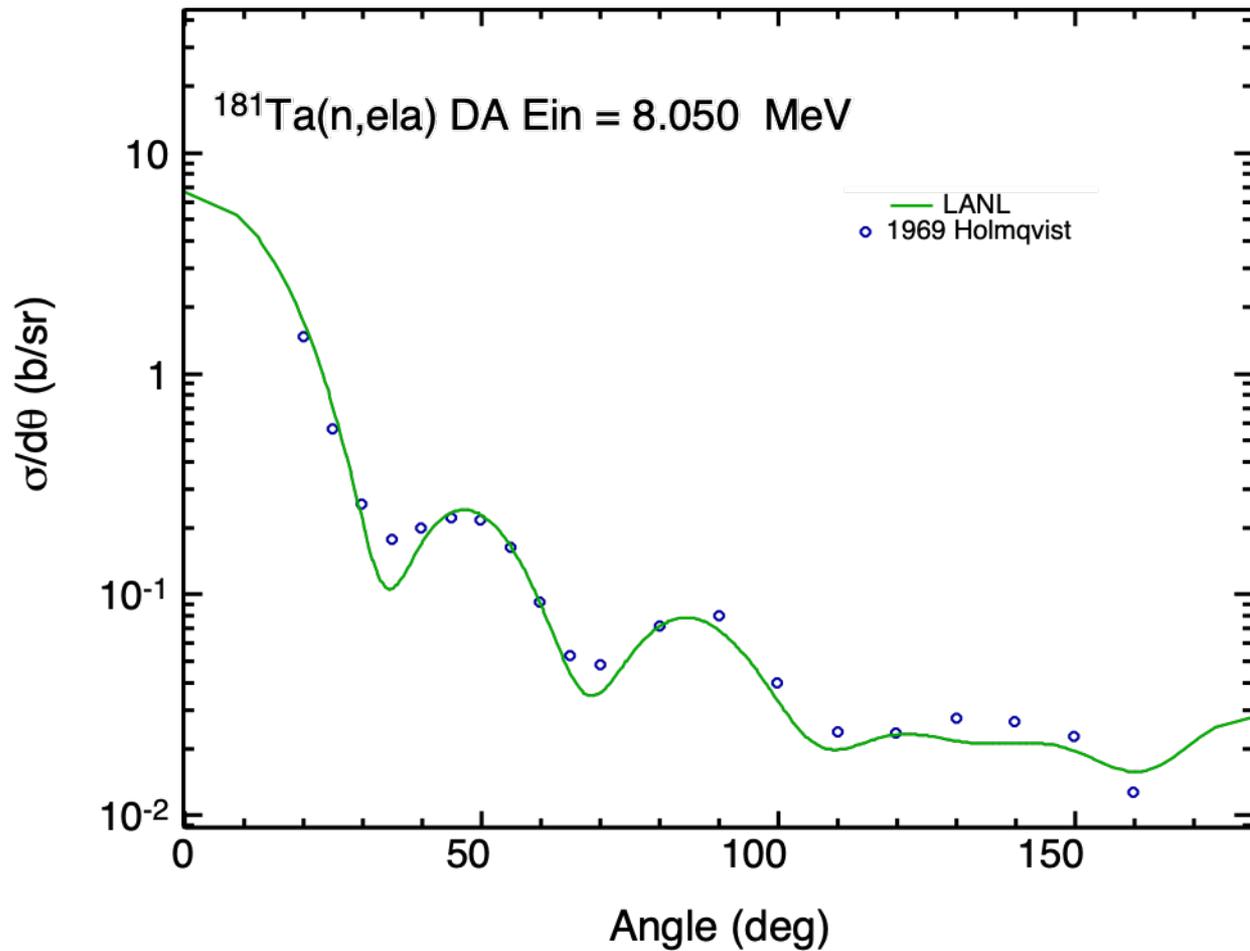

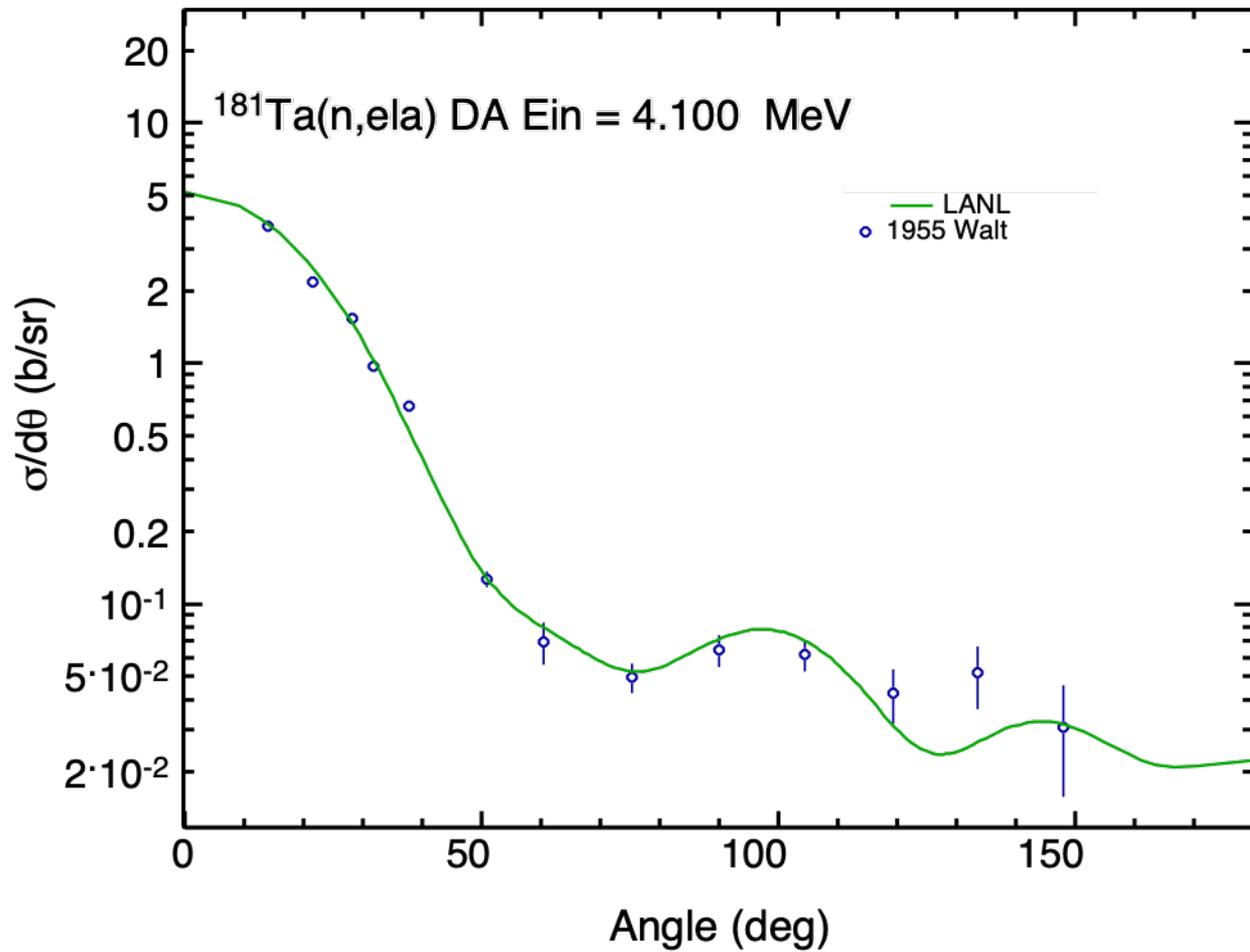

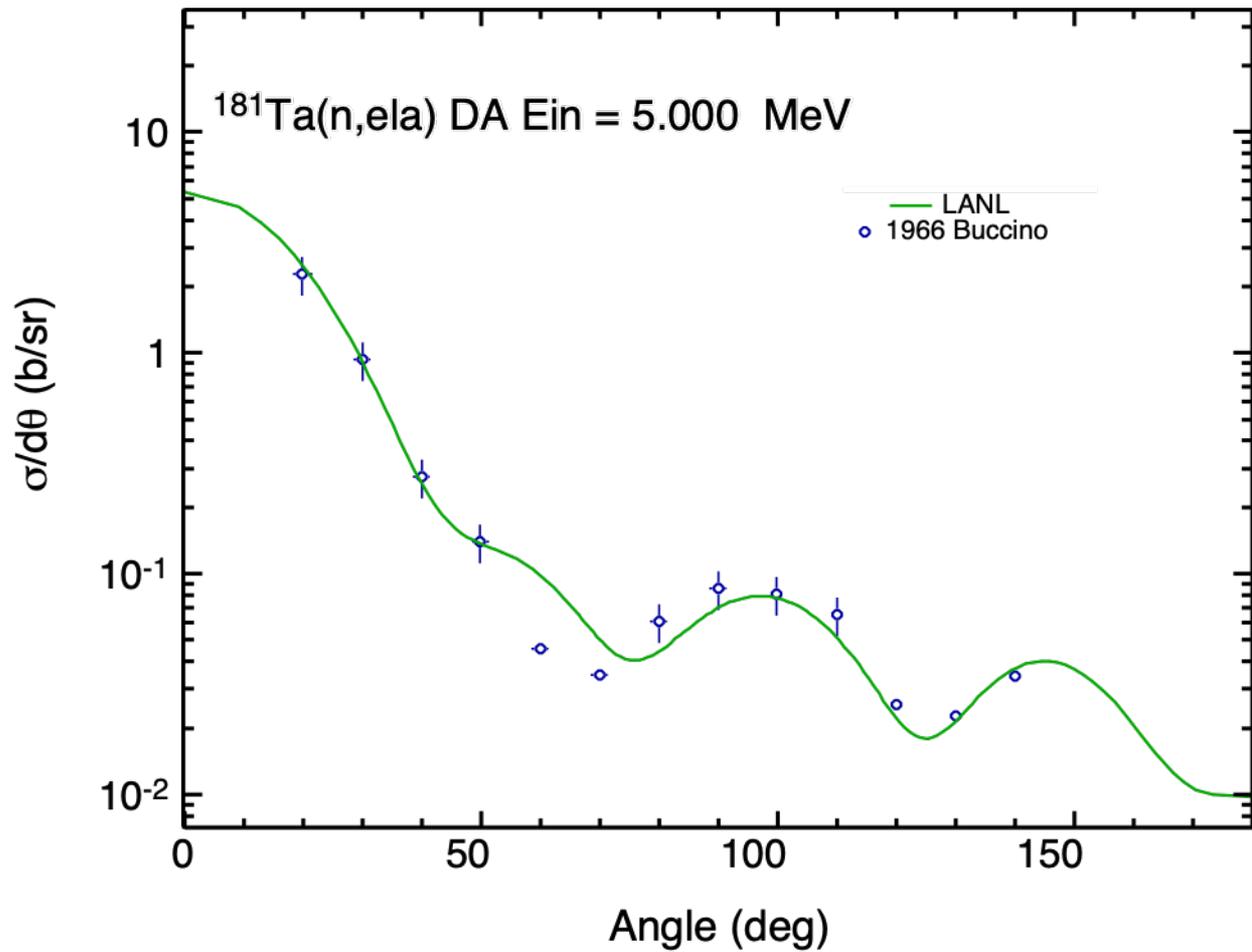

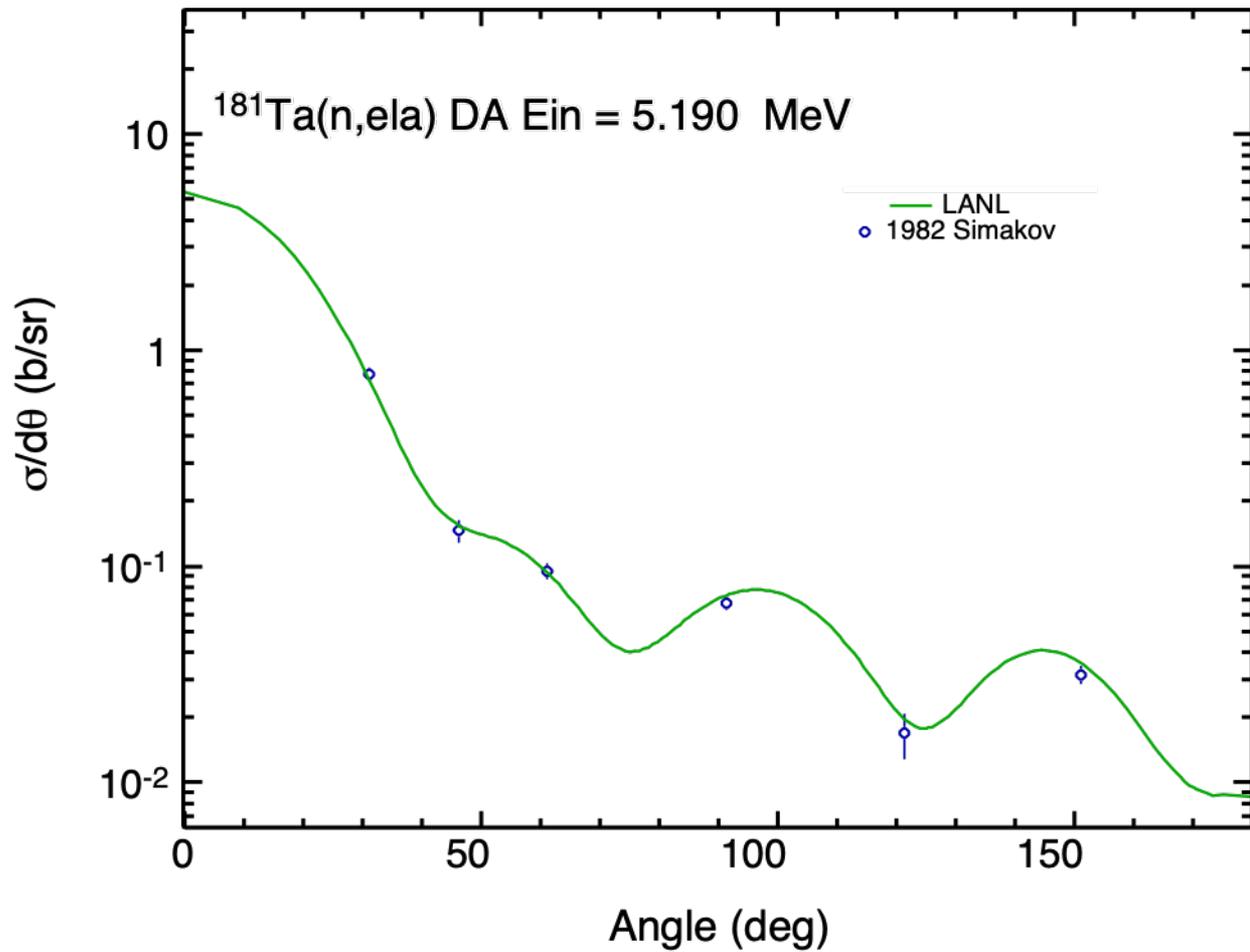

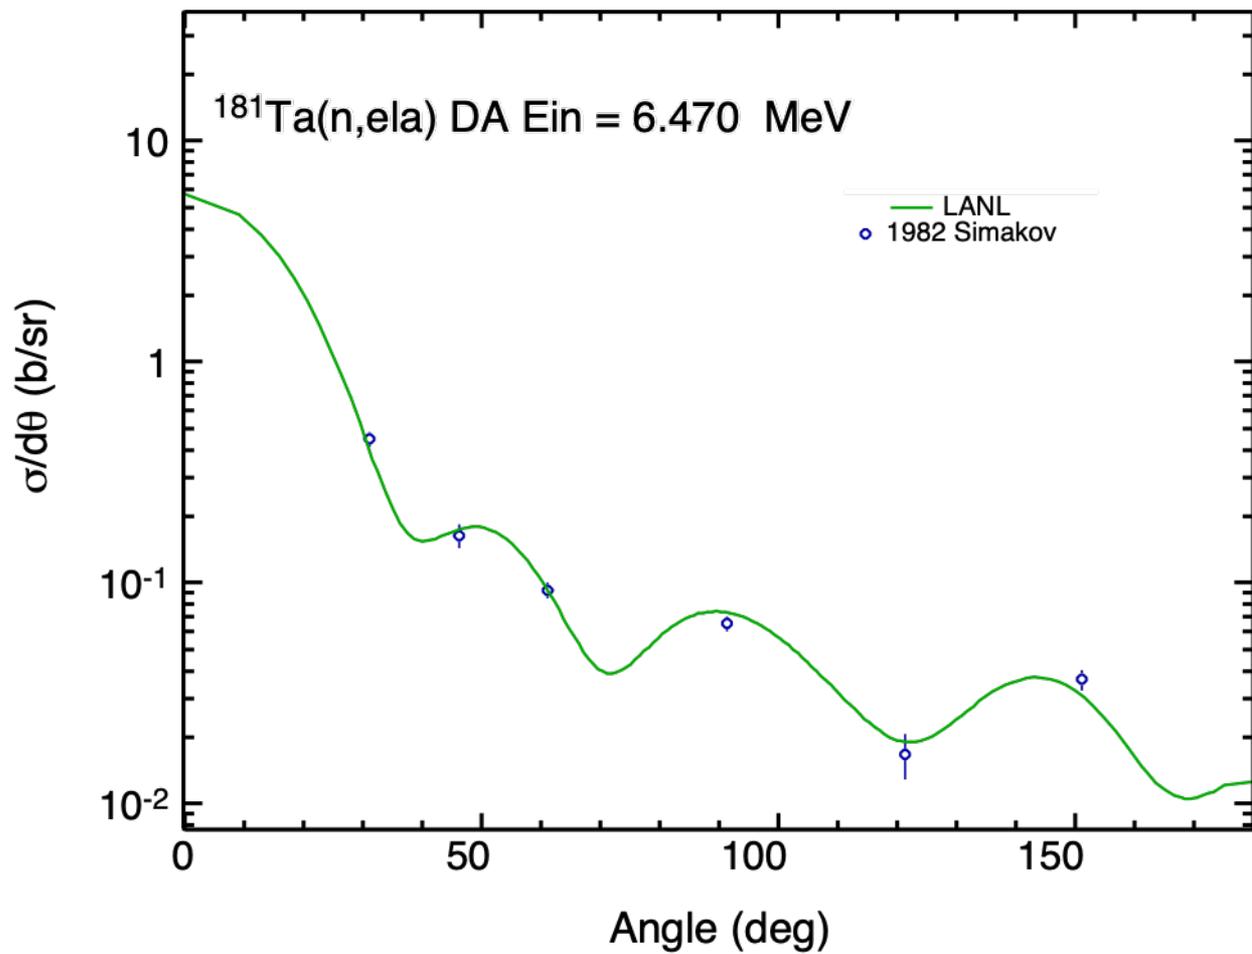

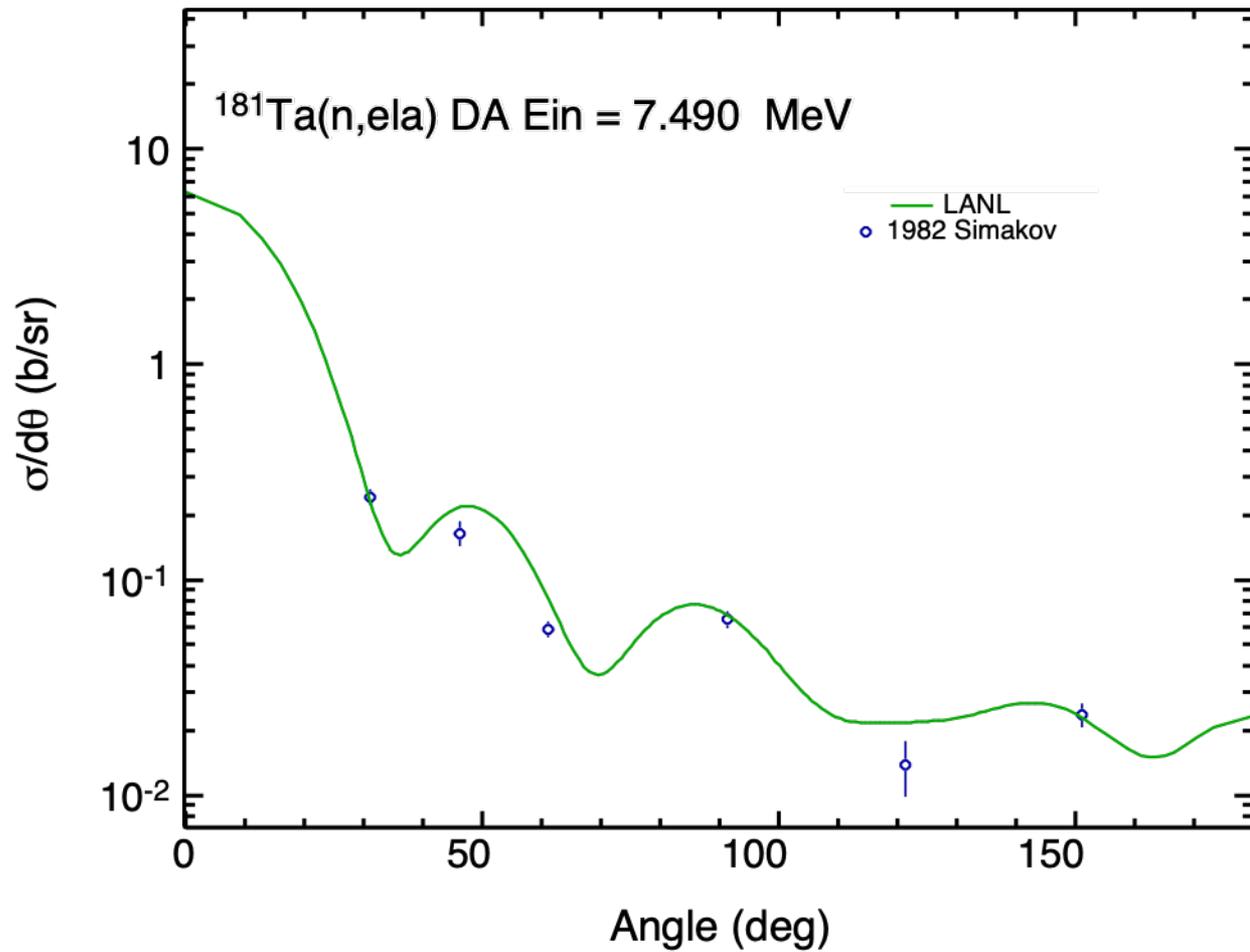

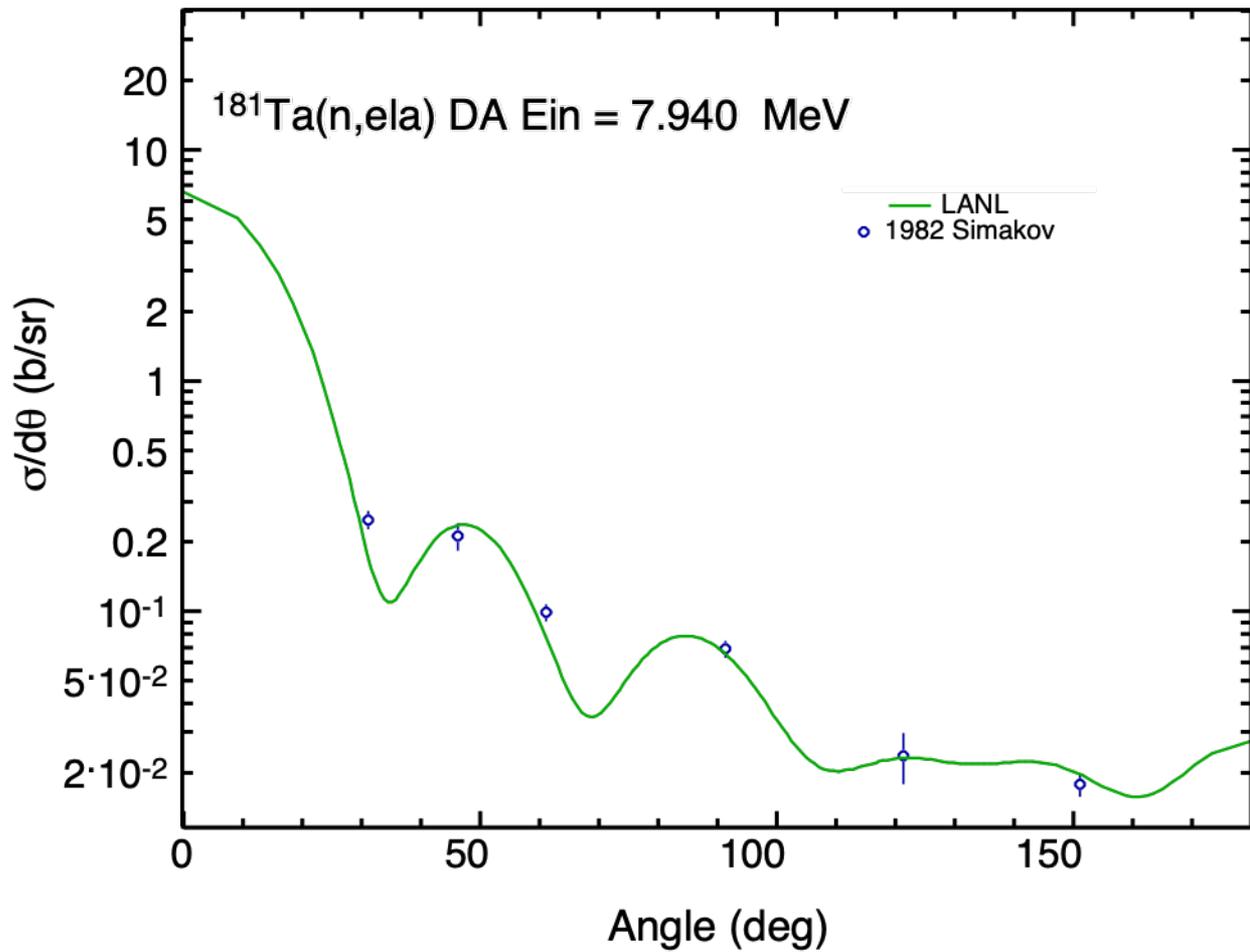

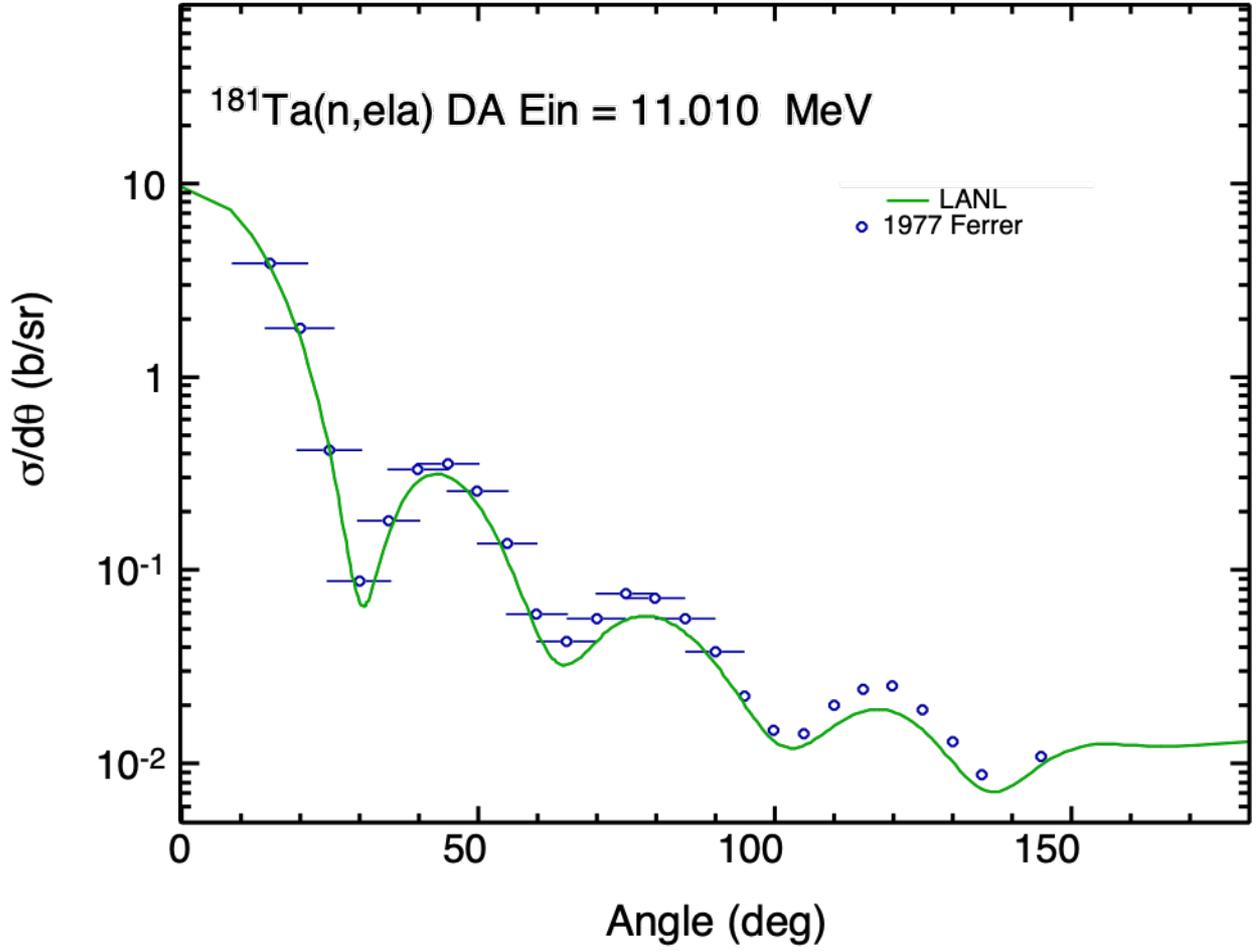

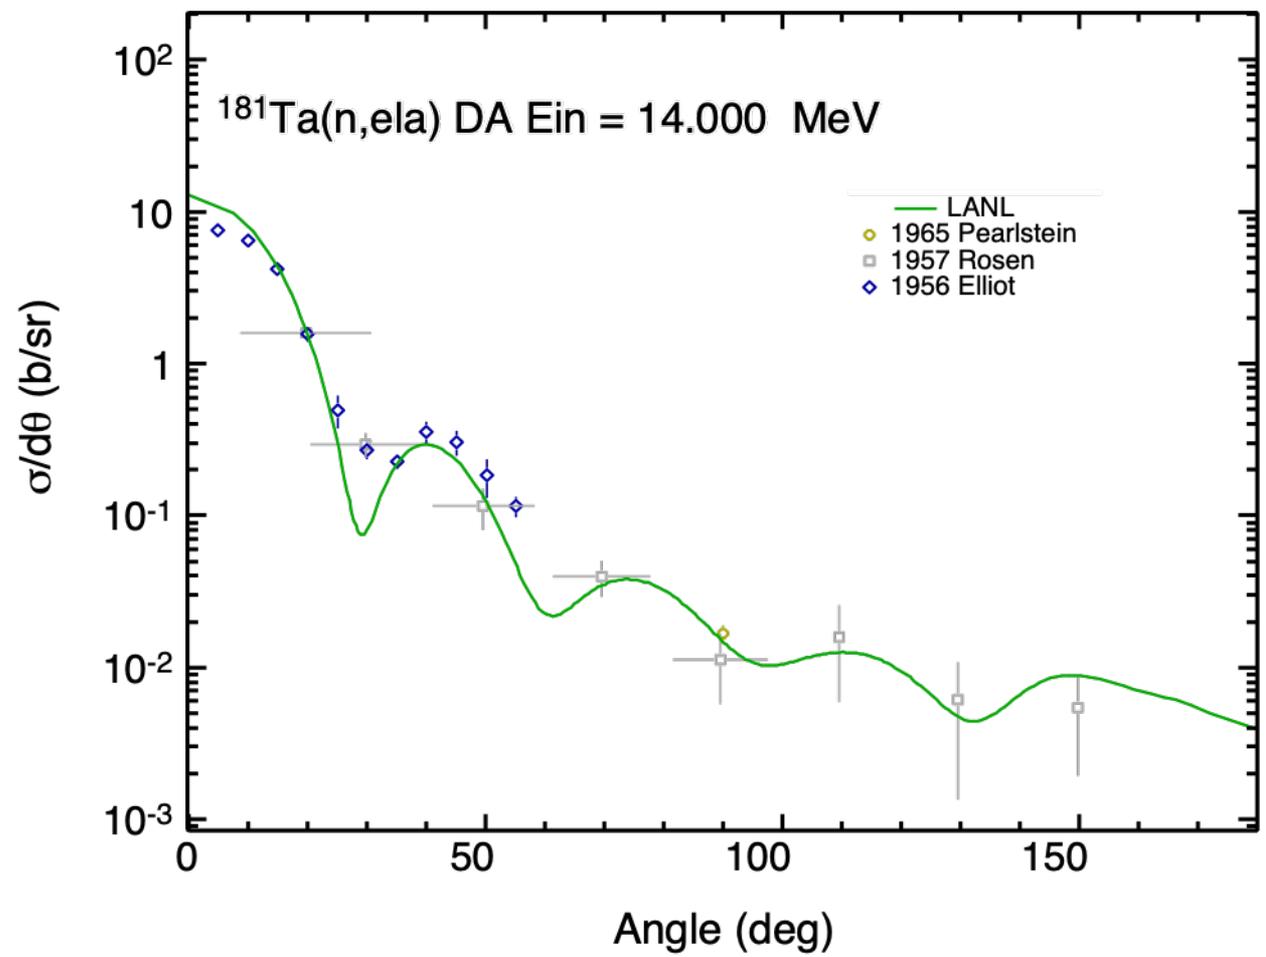

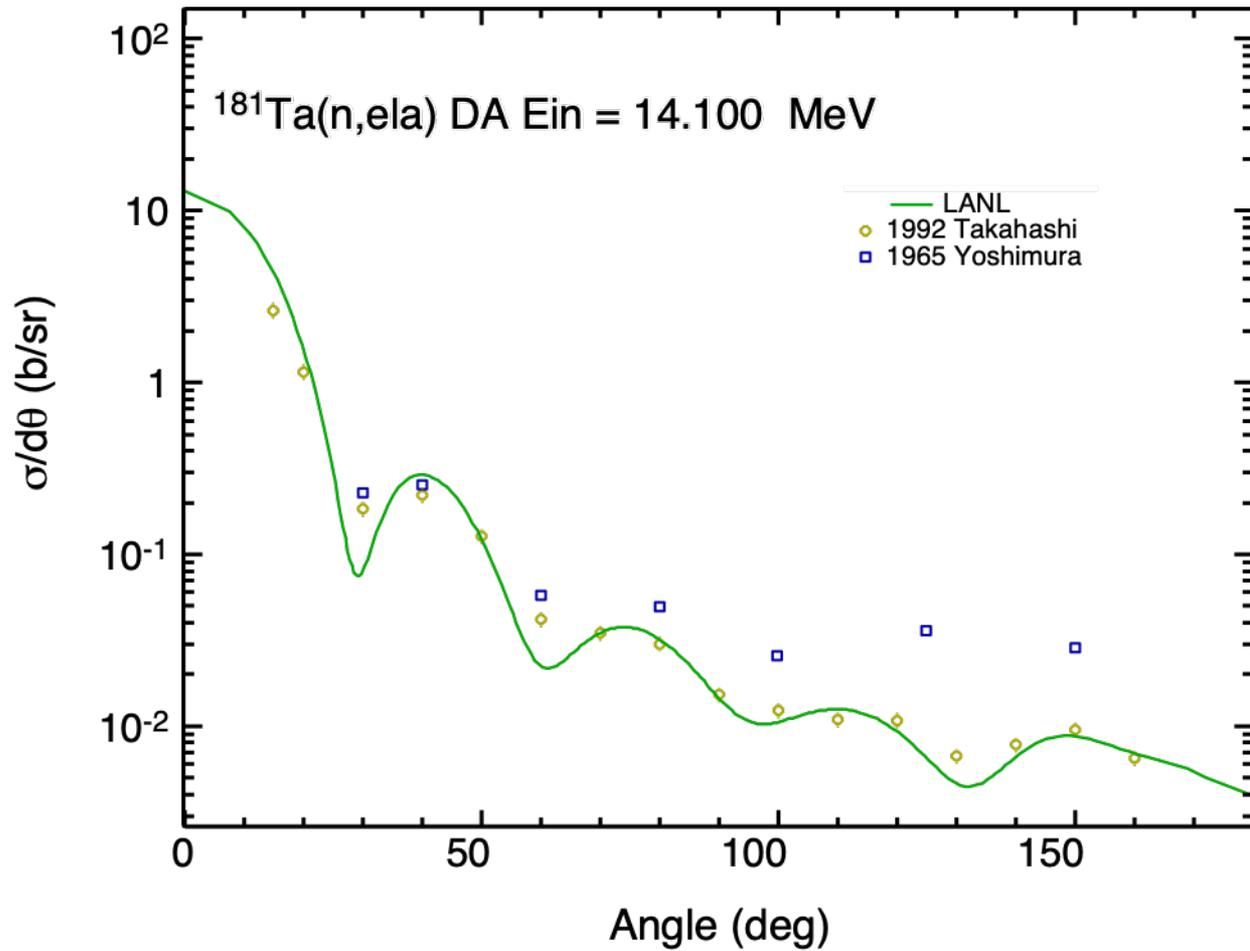

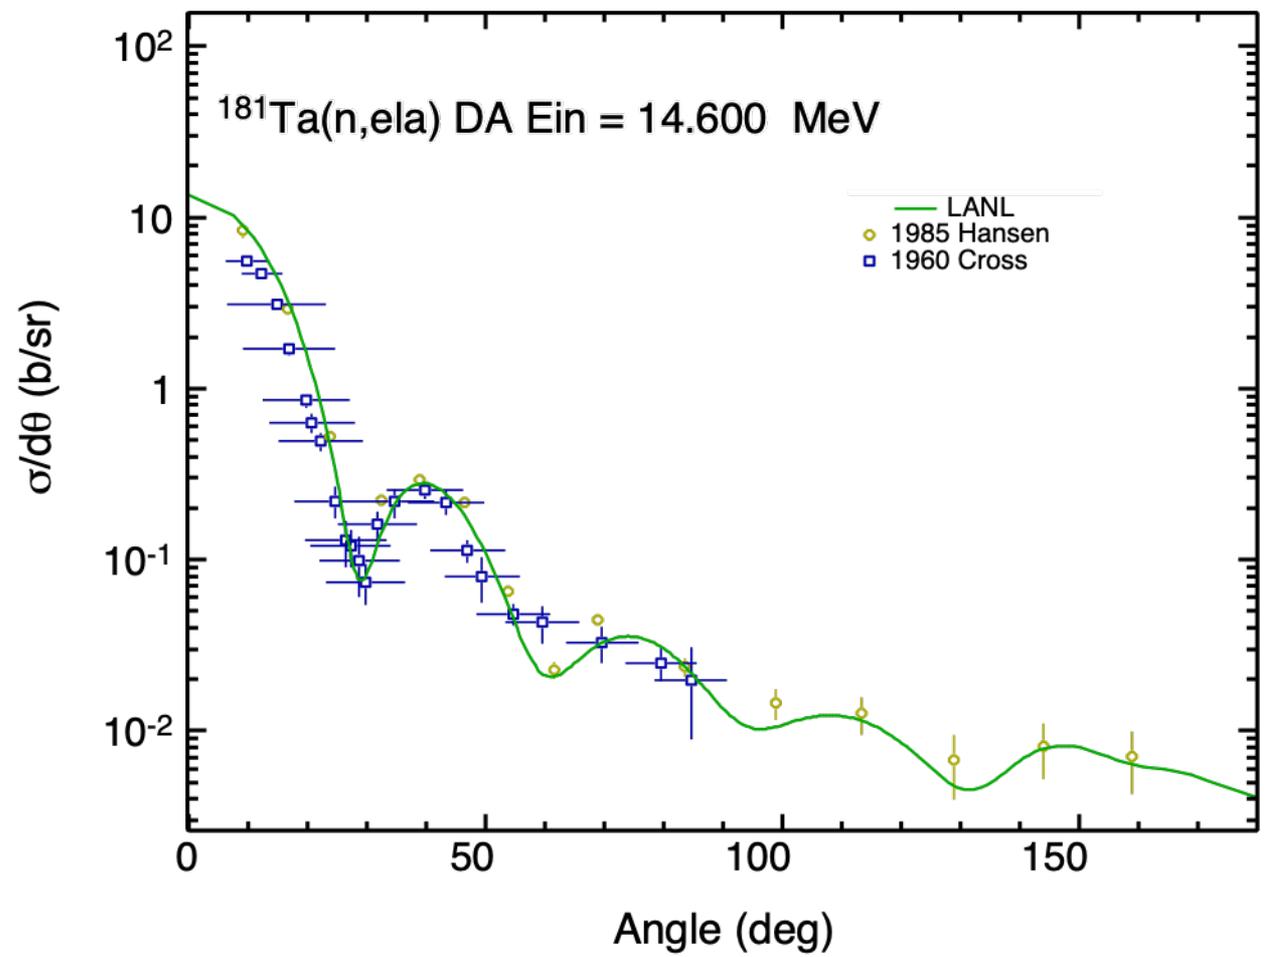

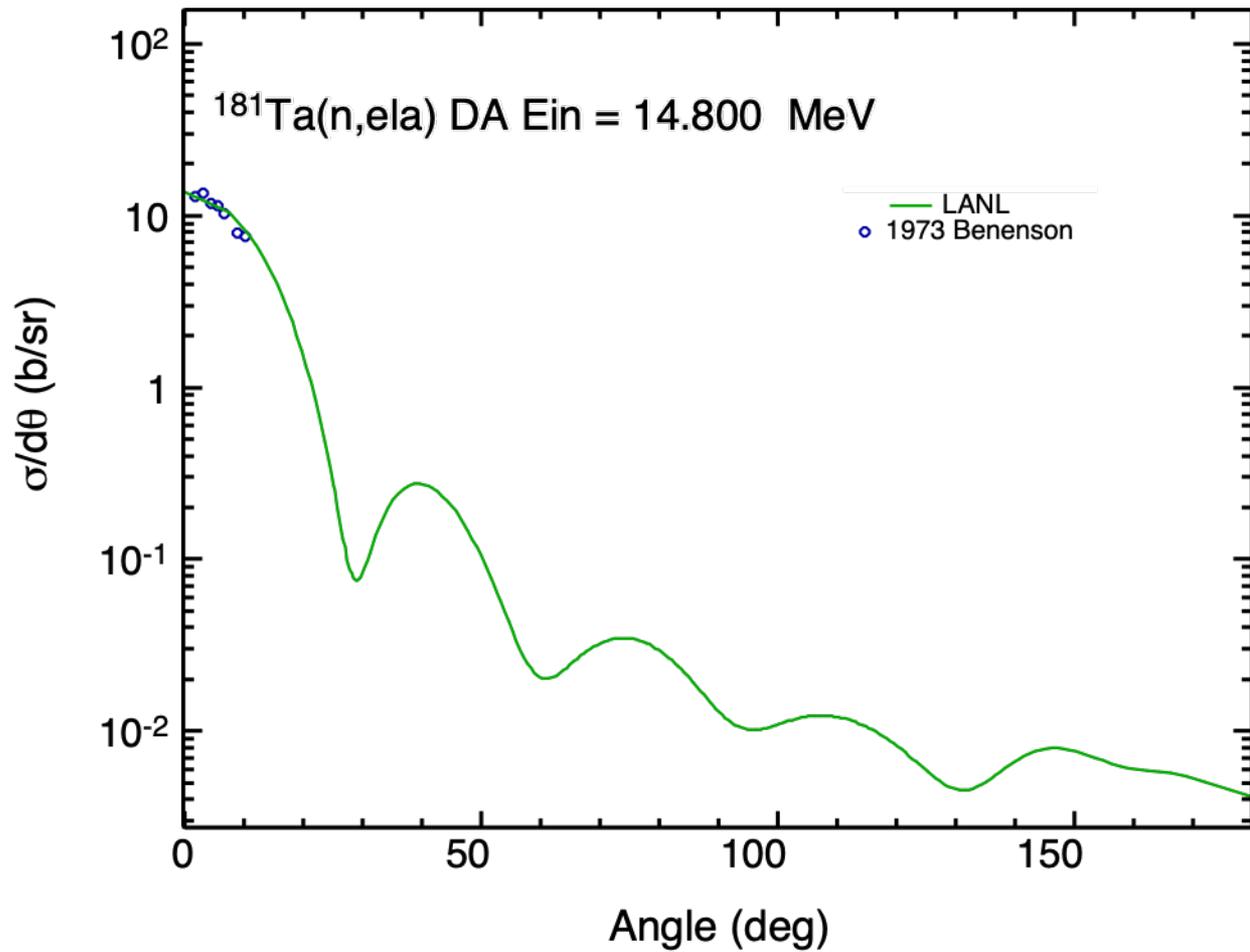

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 11.010$ MeV

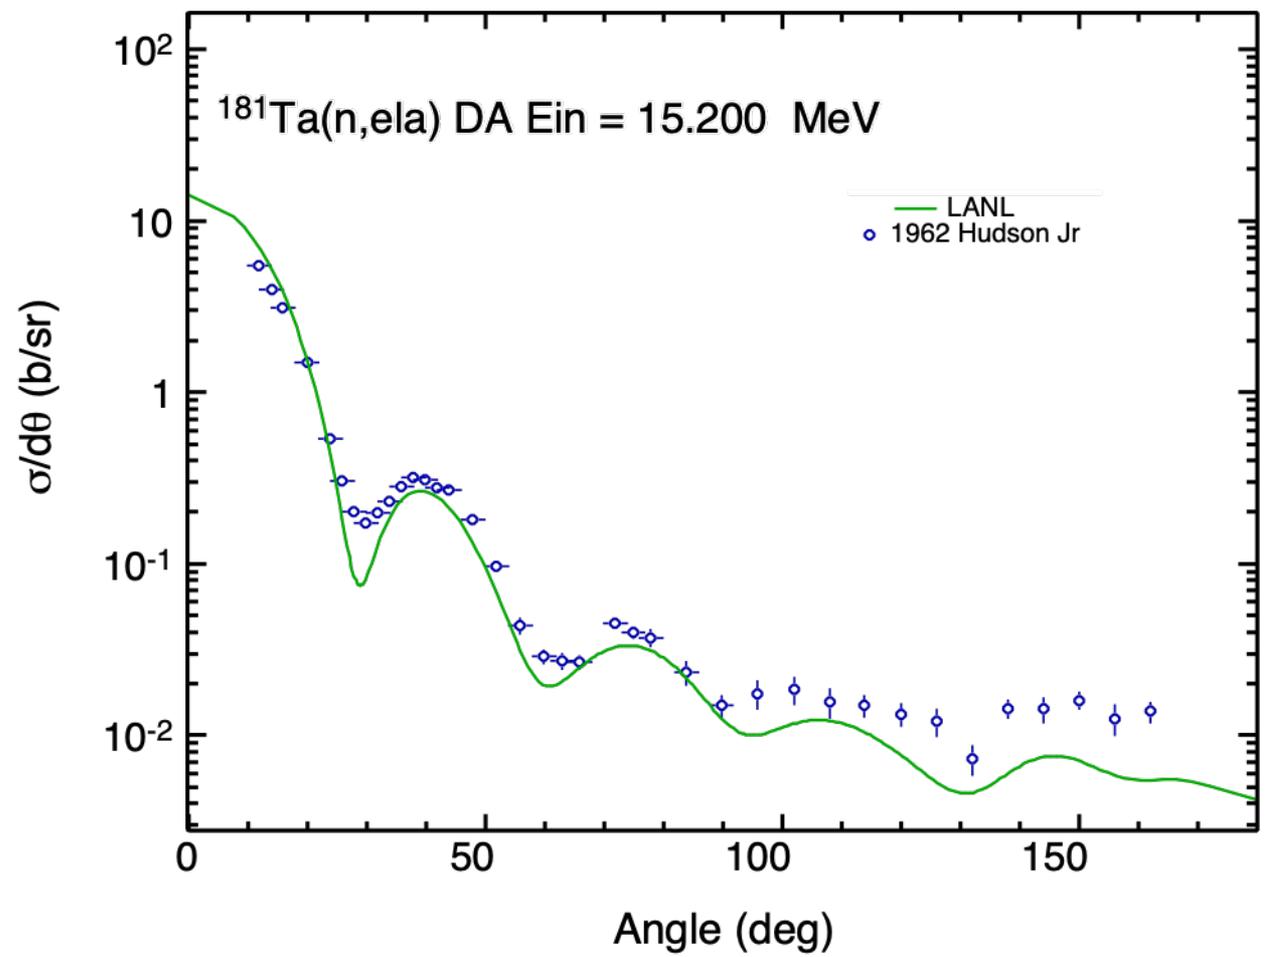

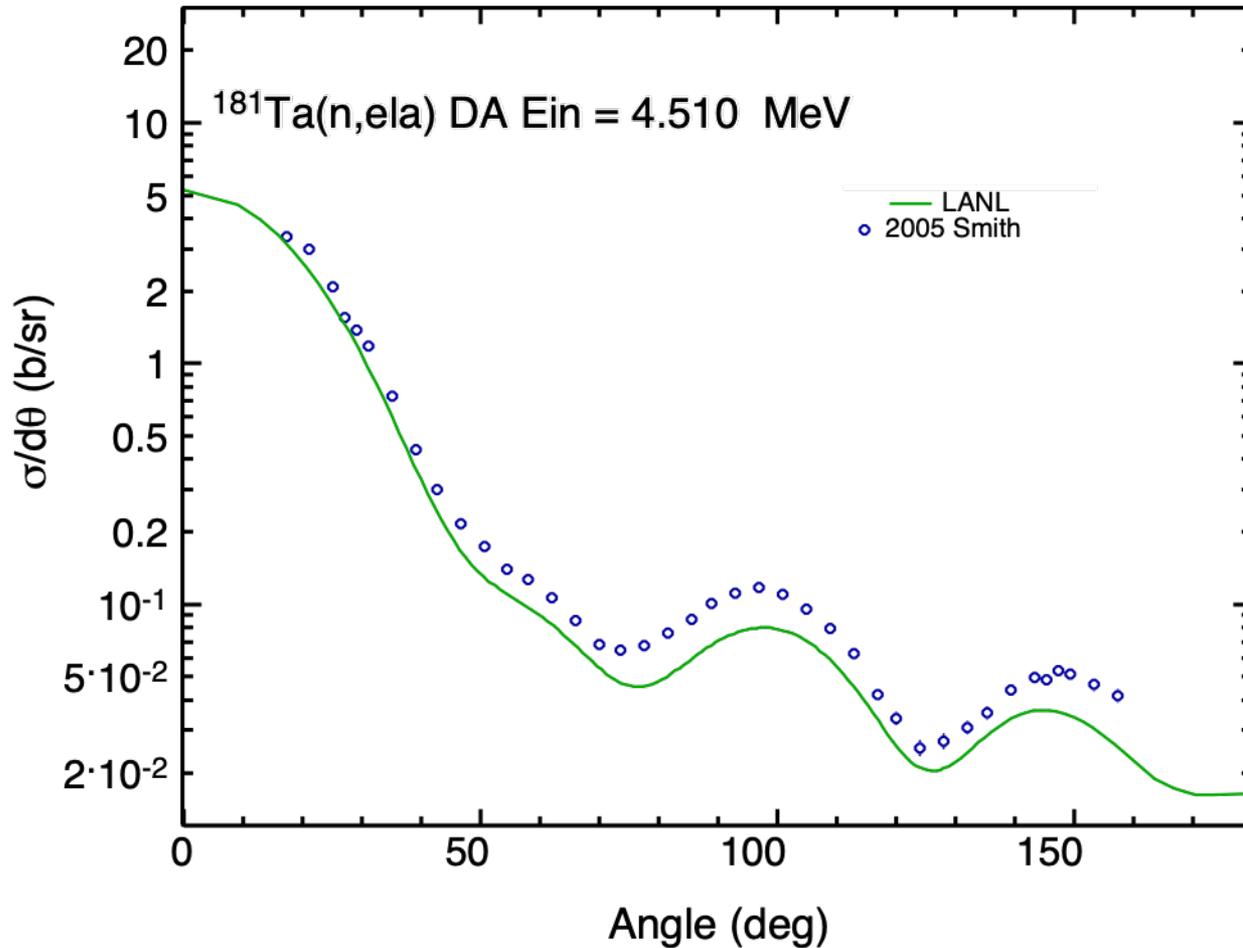

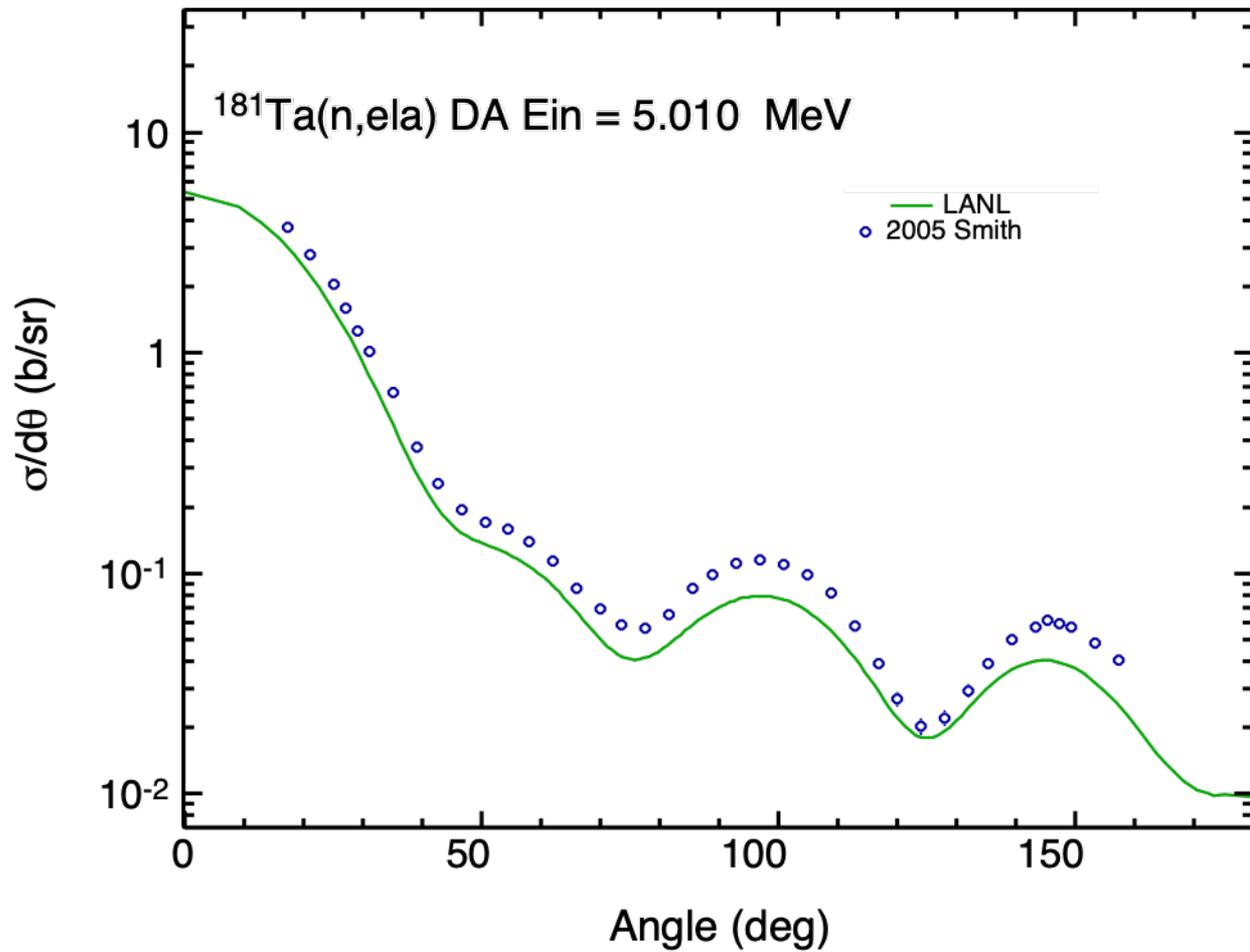

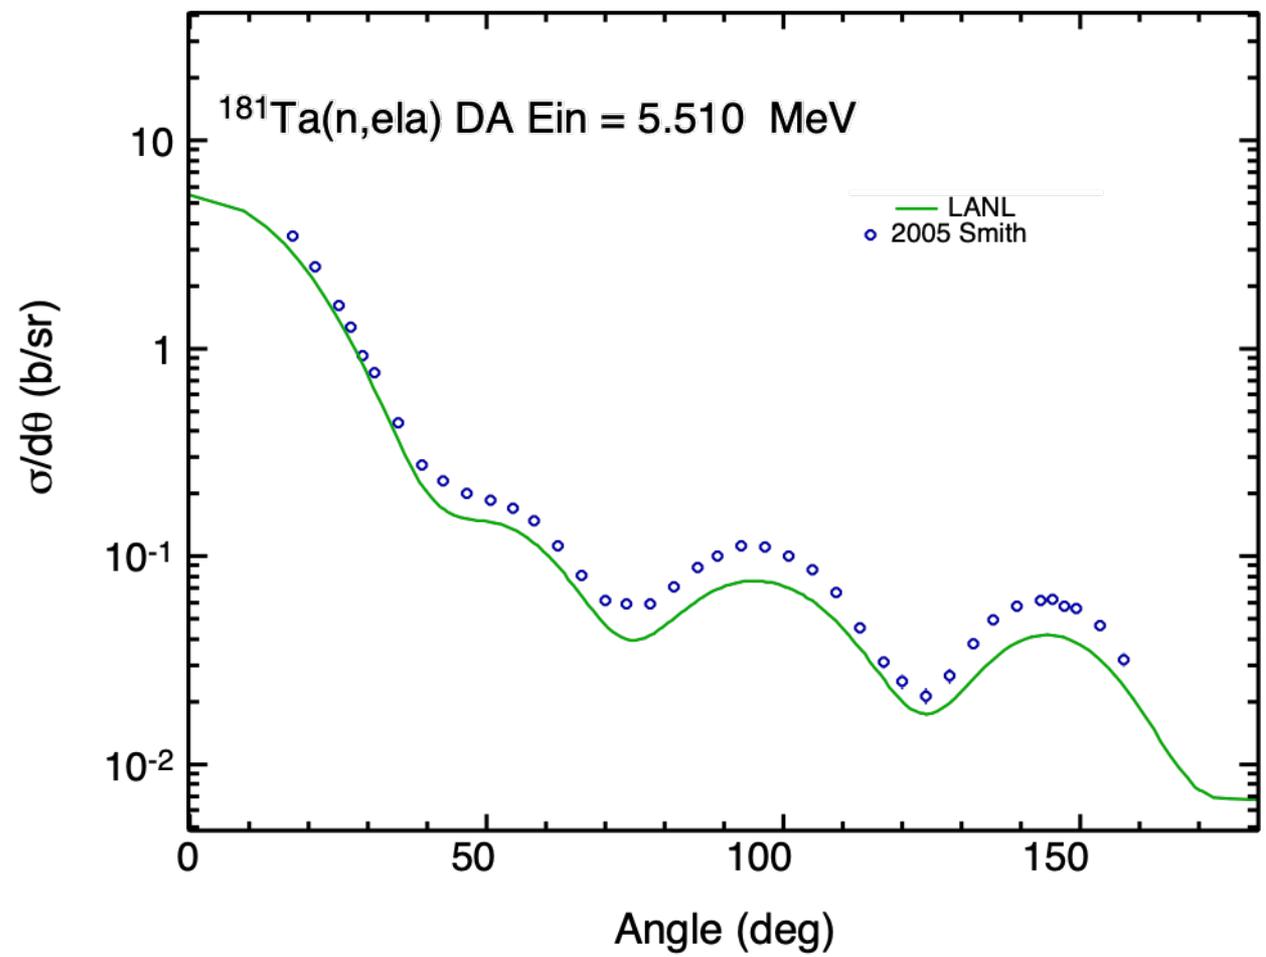

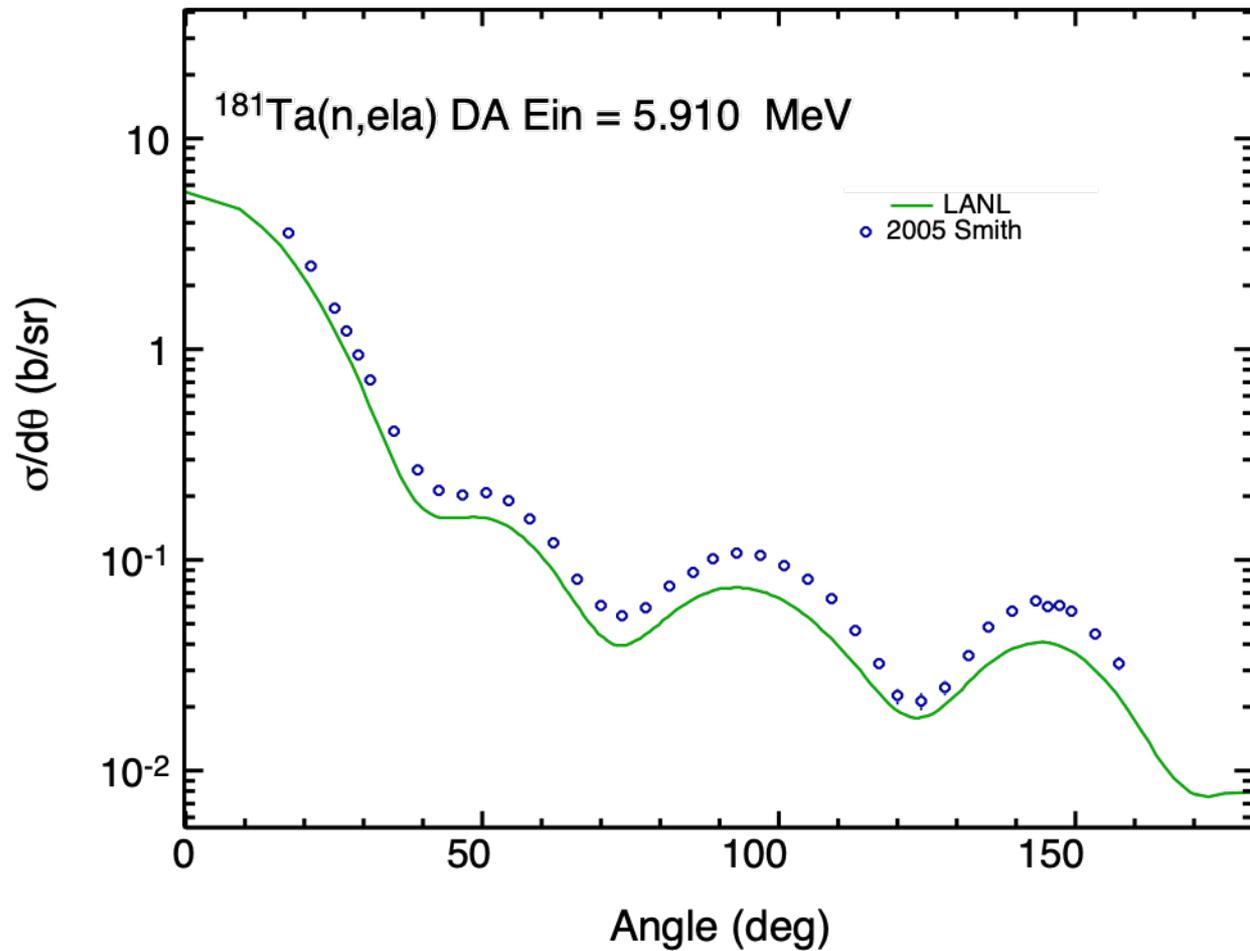

A. Smith: 4.5 - 10 MeV

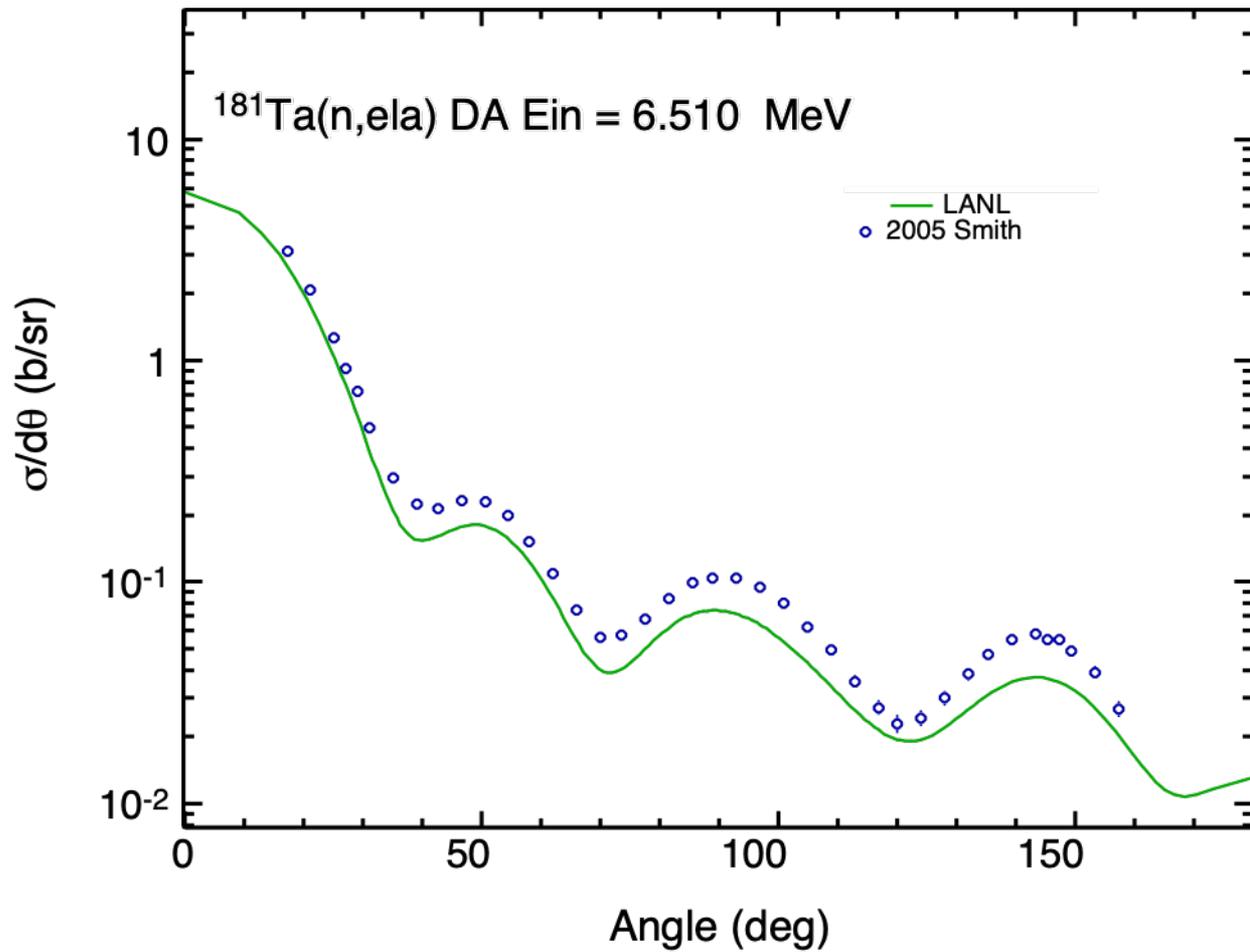

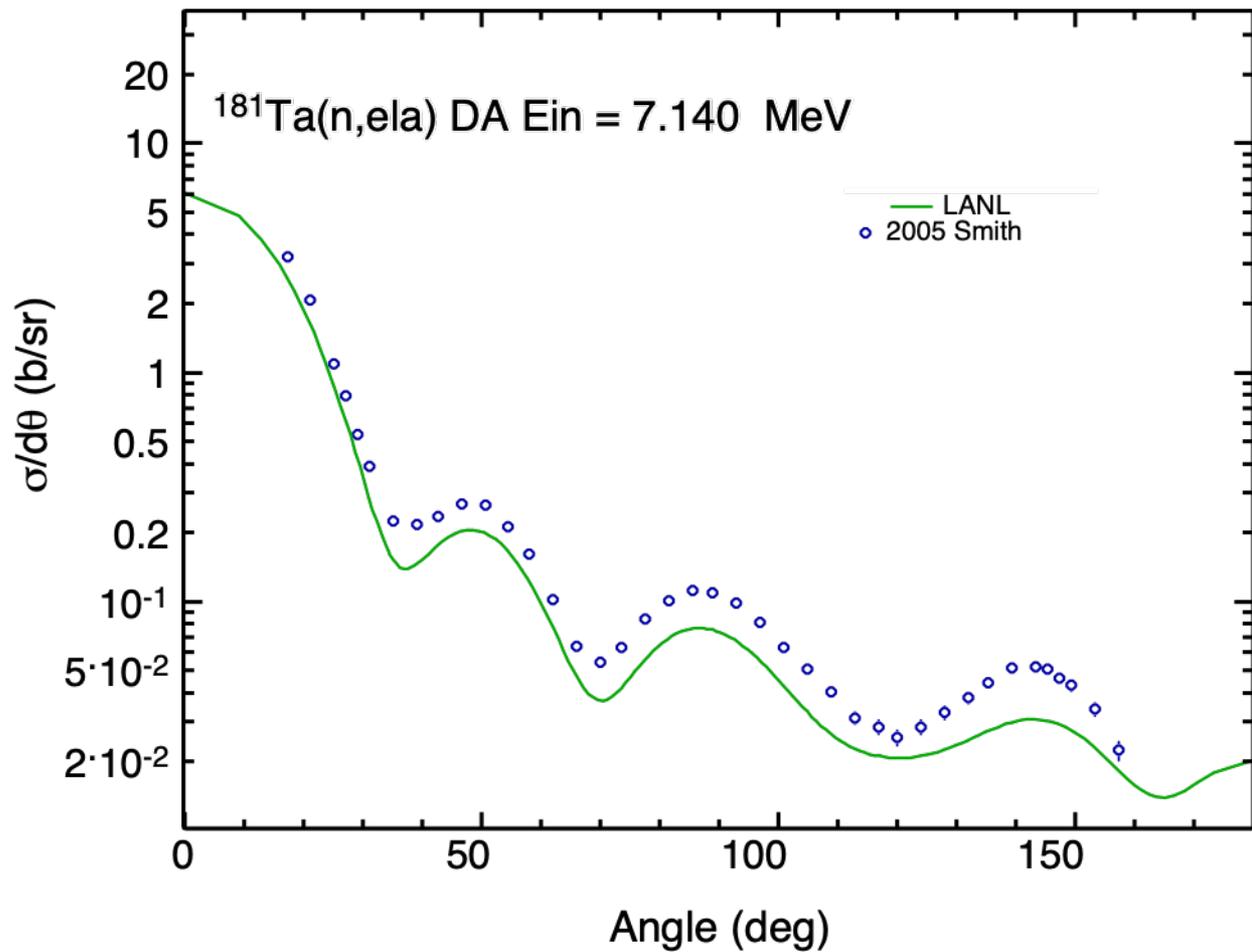

Shape evolution in ~ 0.5 MeV steps.

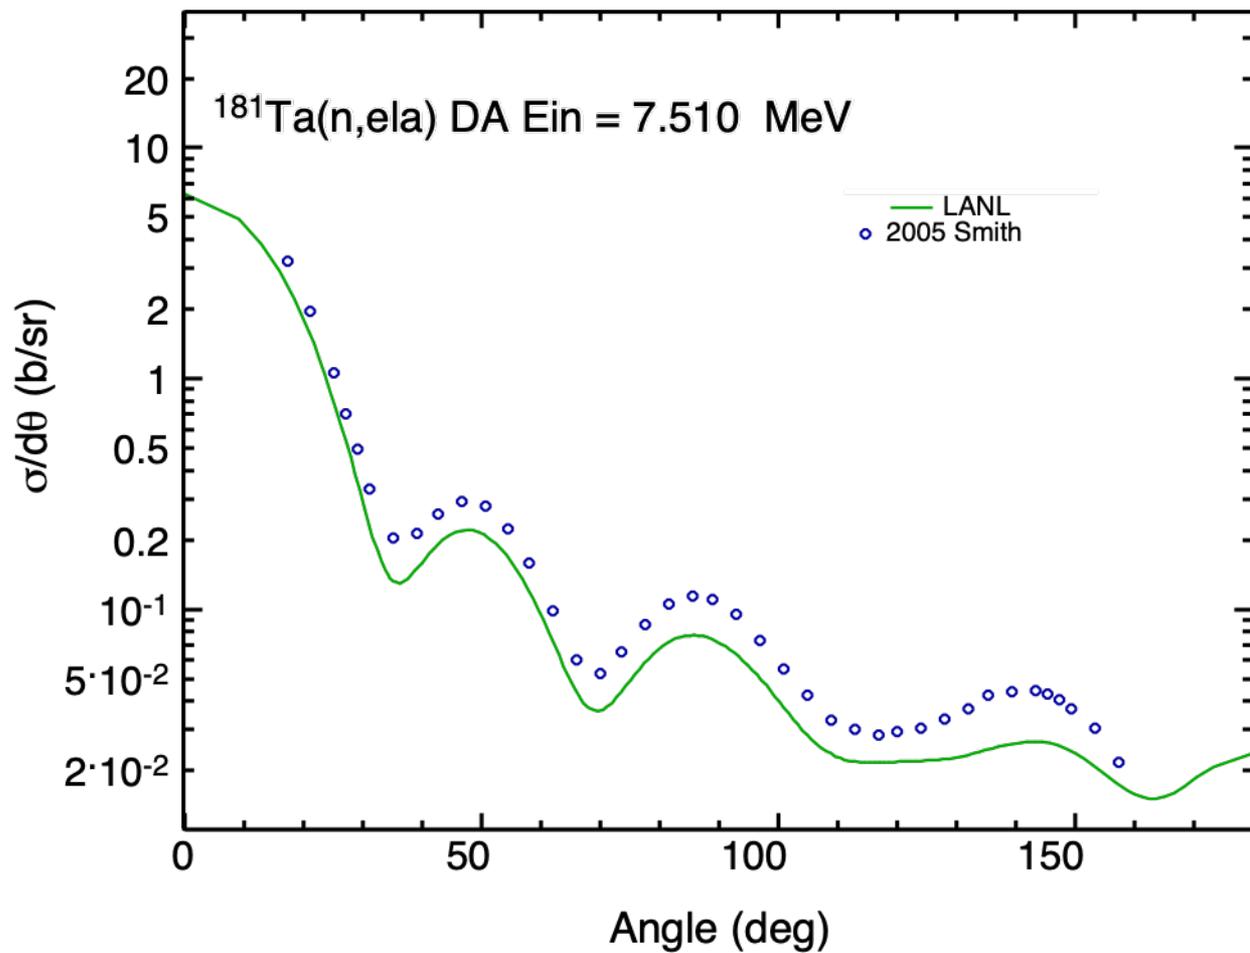

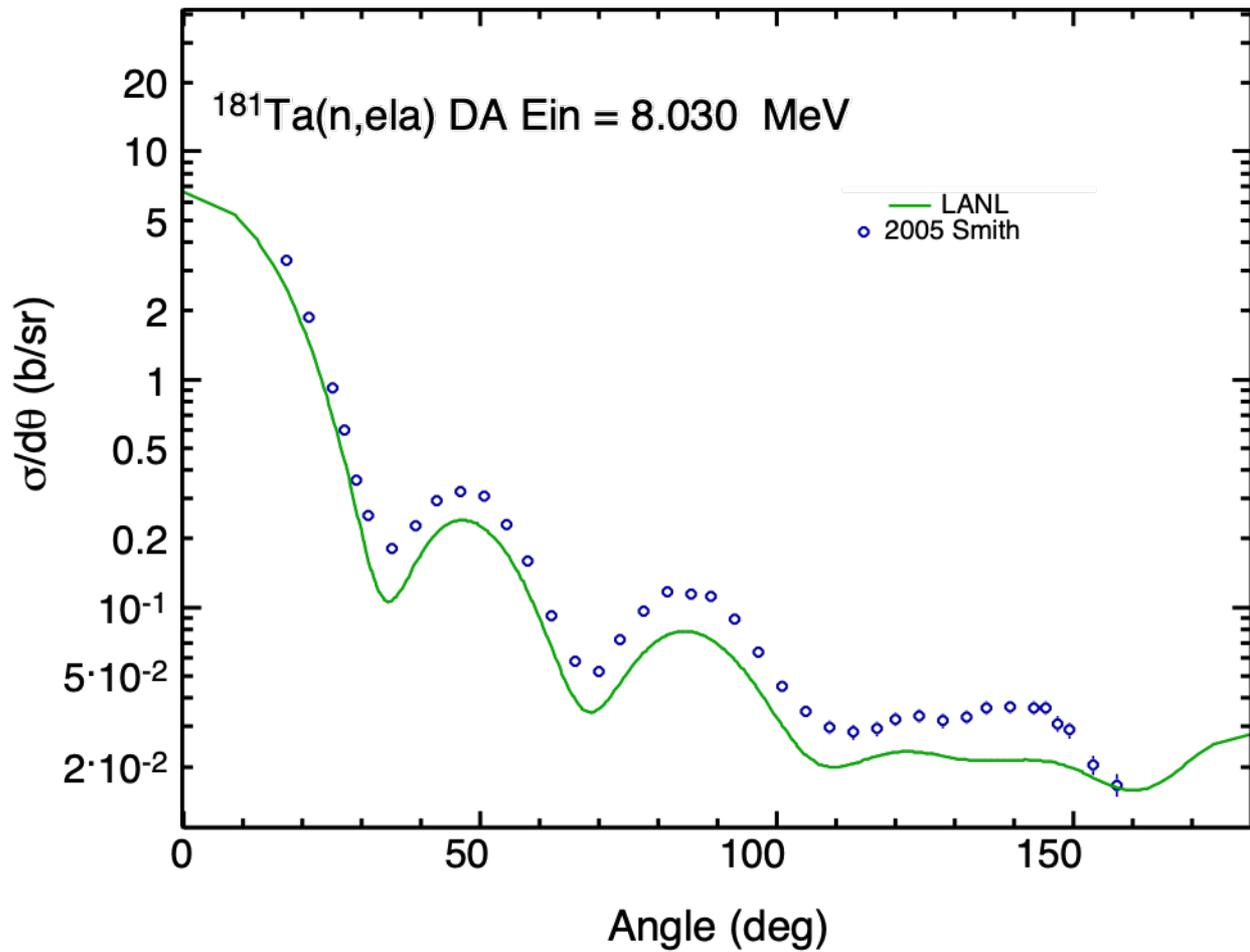

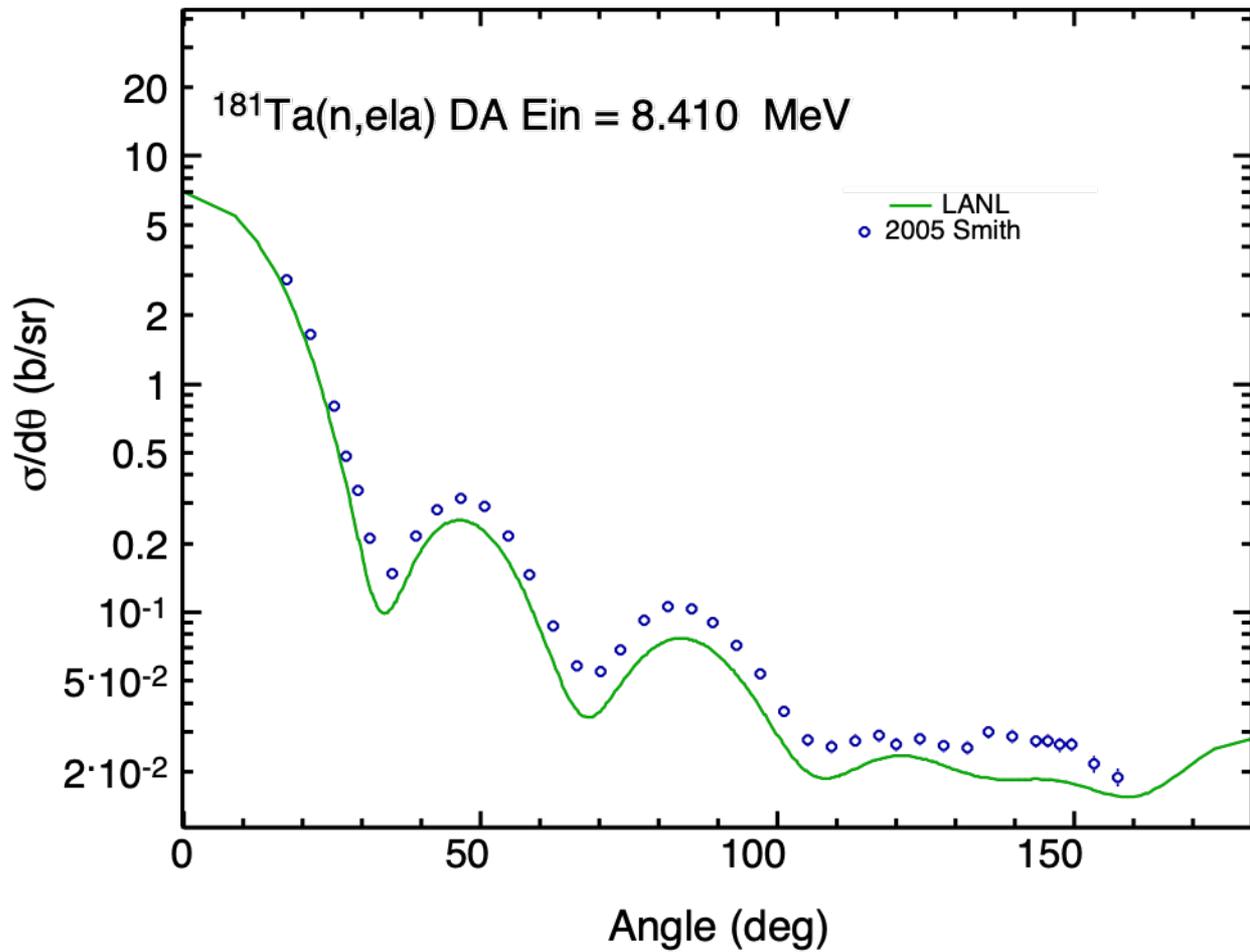

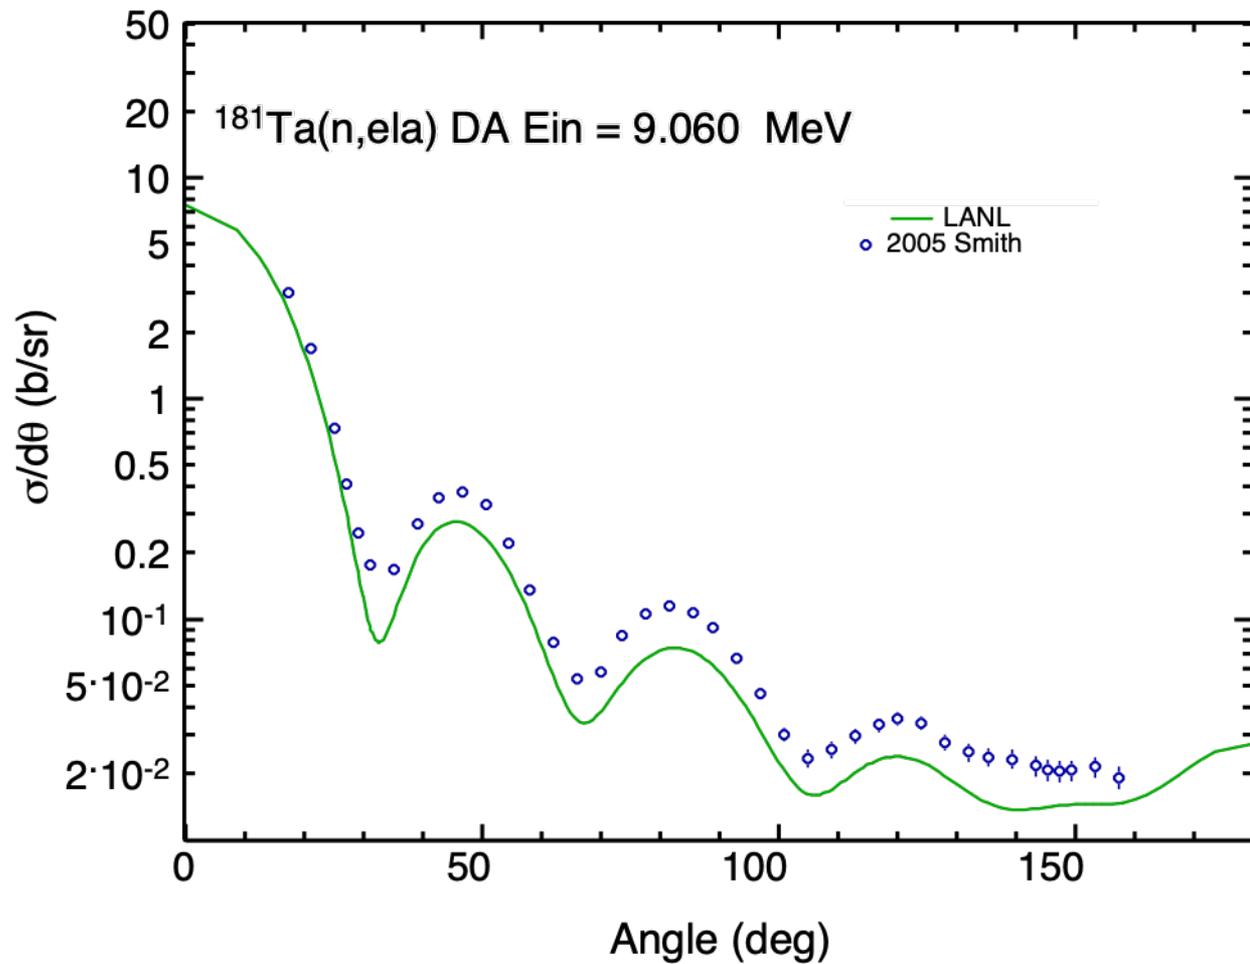

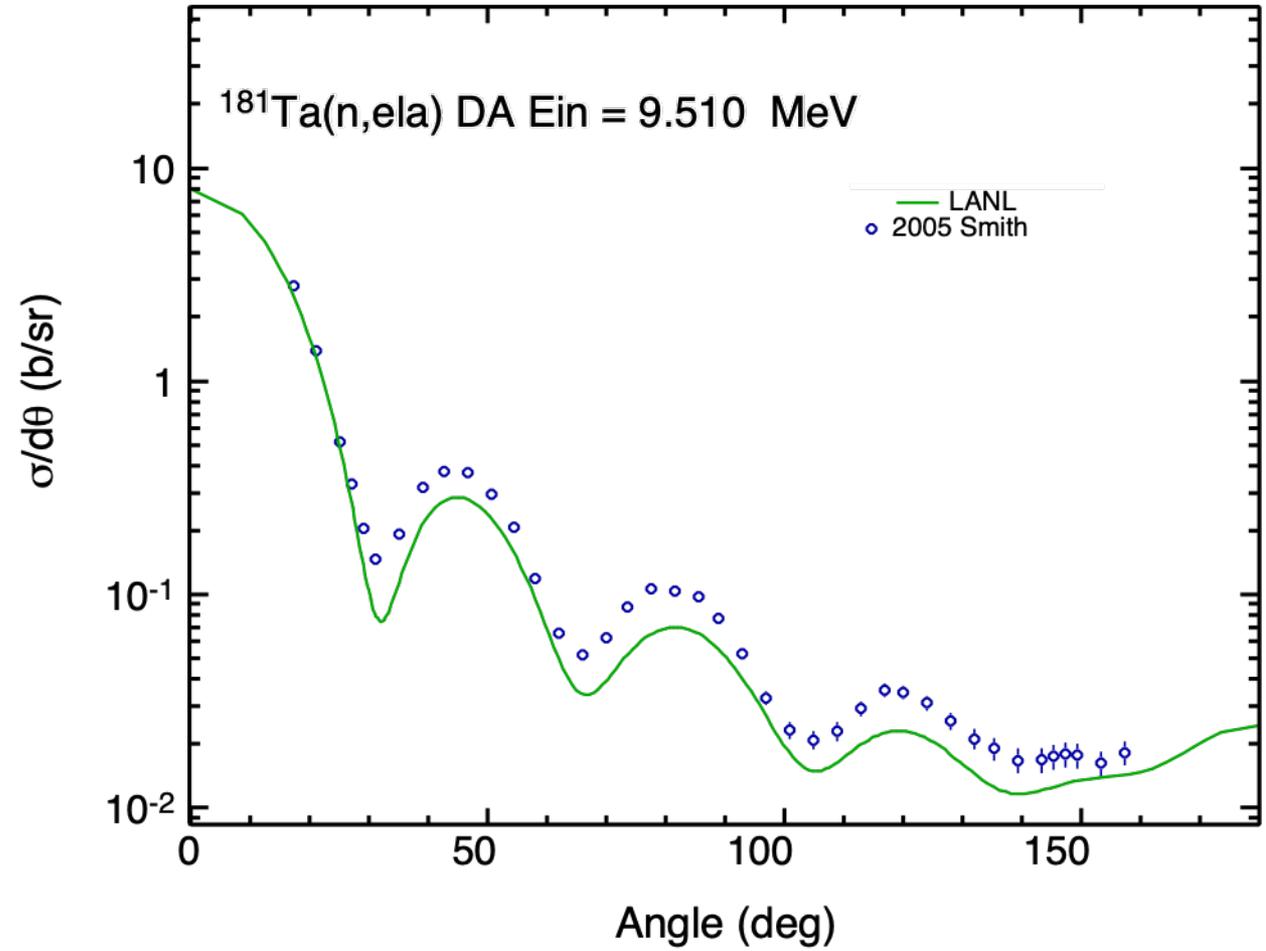

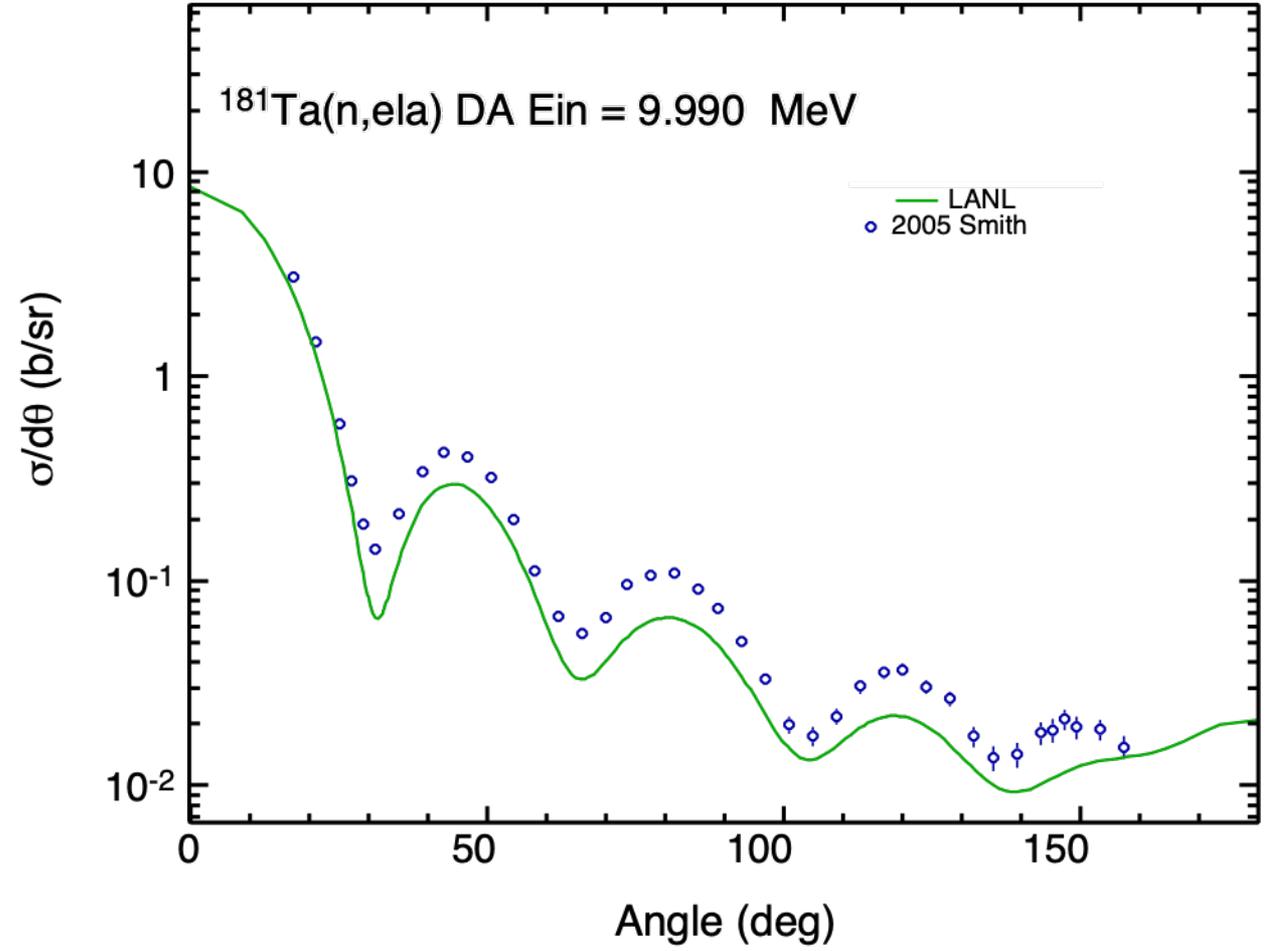

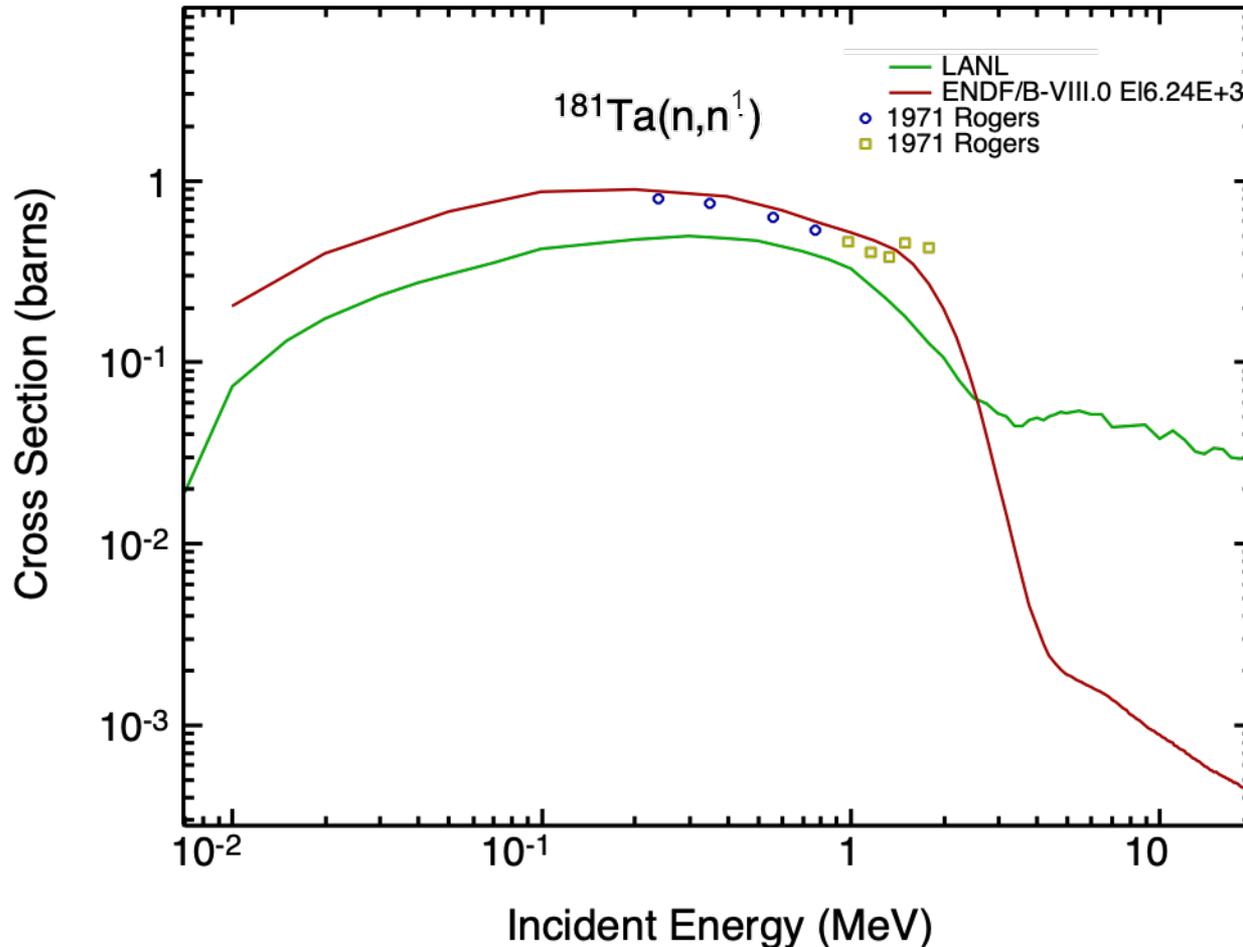

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 9.510$ MeV

$^{181}\text{Ta}(n,\text{ela})$ DA $E_{\text{in}} = 9.990$ MeV

CC model - inelastic x-sec

The 1-st inelastic (summed into elastic) does not belong to the ground state rotational band. The DWBA has been added to increase elastic angular distr. at higher energies (disregard numerical fluctuations)

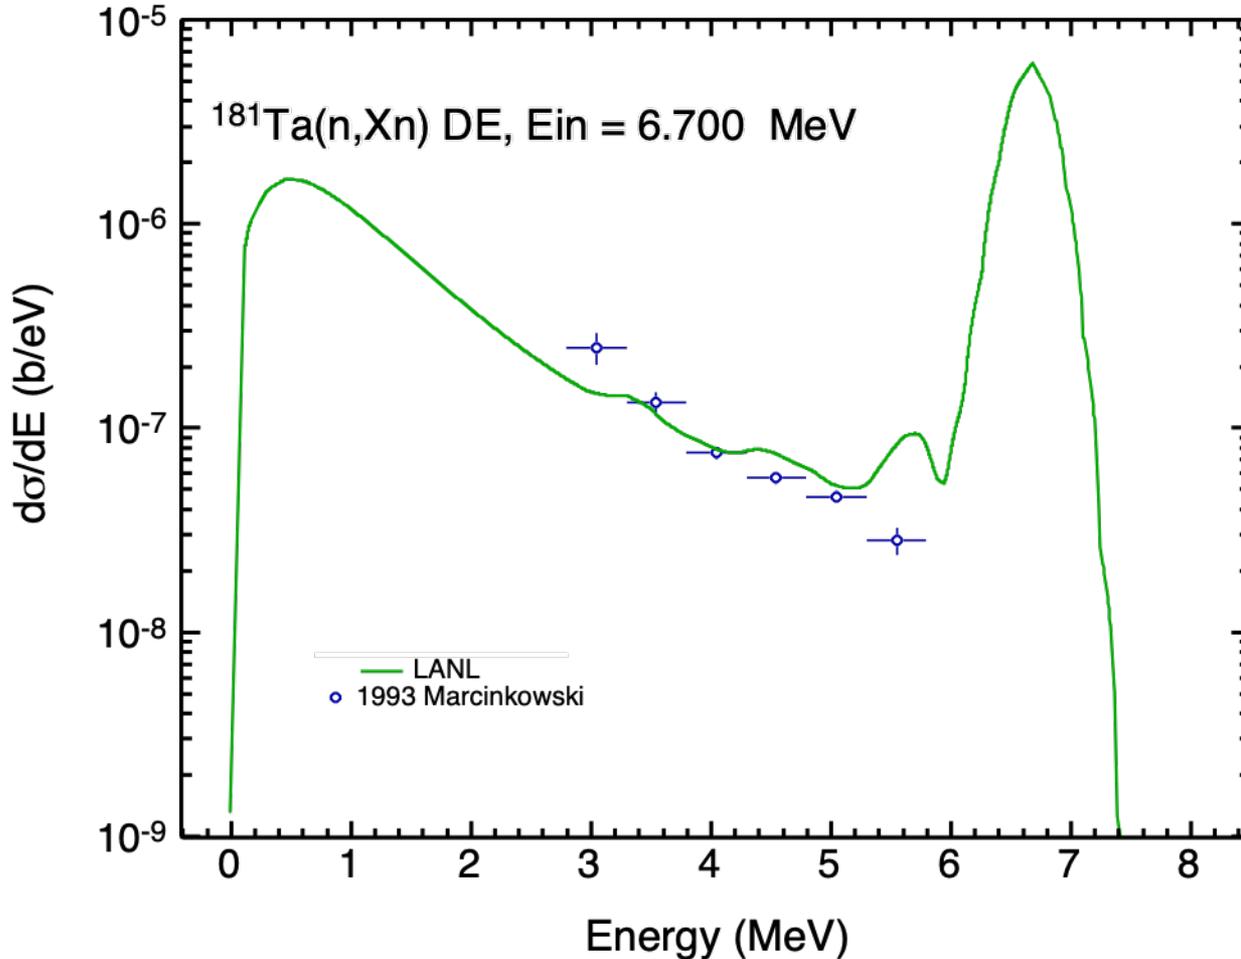

VIII.0 cross sections are higher for this and other inelastics and agree better with experiments but.. it comes at a price of overshooting total by ~ 0.5 b.

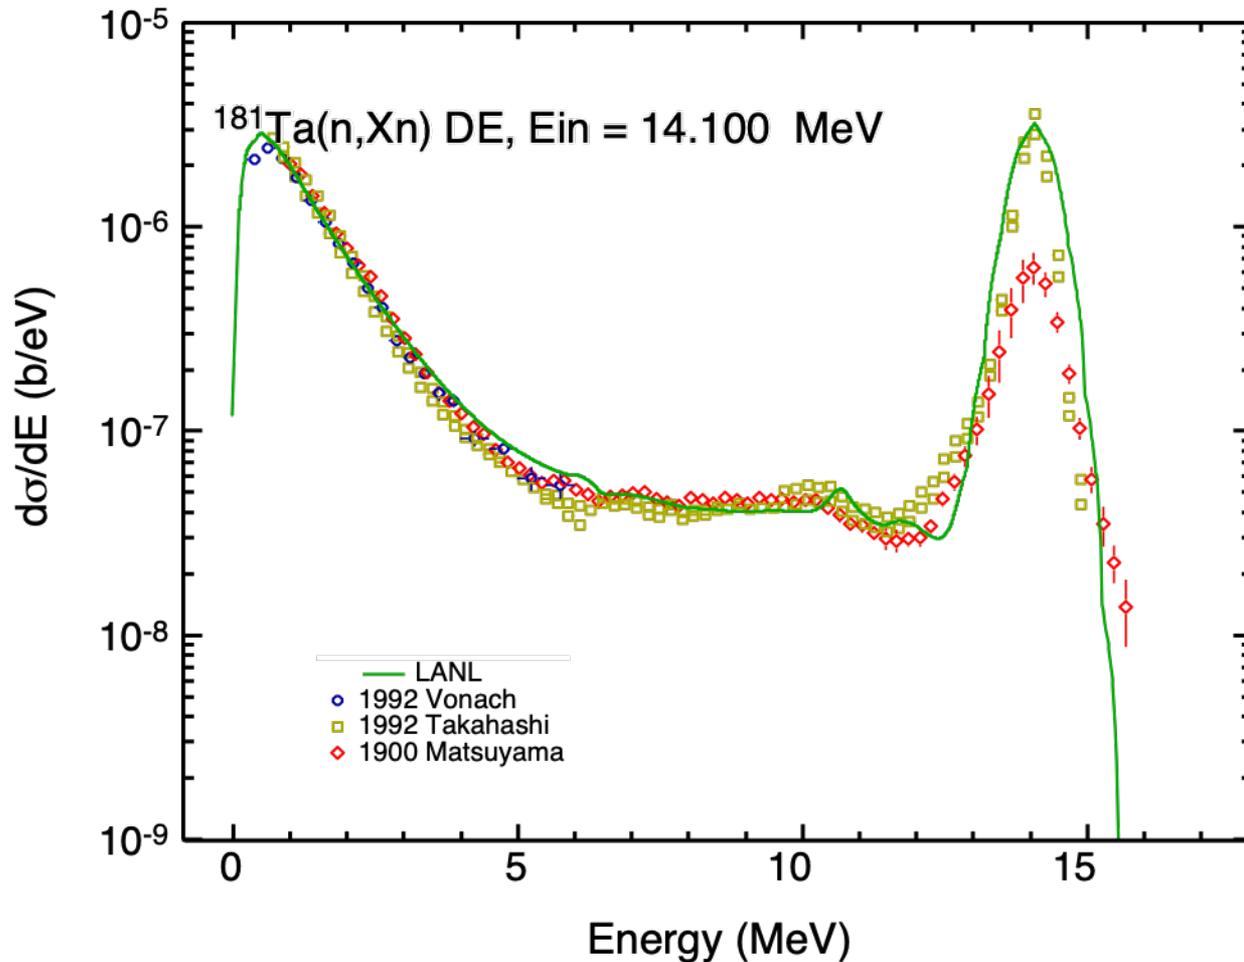

MSD/MSC - neutron spectra, inelastic & (n,xn)

- Quantum mechanical Multistep Direct (MSD) and Multistep Compound (MSC) were employed for neutron emission instead of the exciton model.
- MSD eliminates the need of adding large number of collective discrete levels to the continuum. Default calculations were pretty good but adjusting (manually) a single parameter brought additional improvement.
- Extensive experimental coverage of DDX from 5 to 20 MeV of incident energies at different angles was essential for building confidence in the calculations.

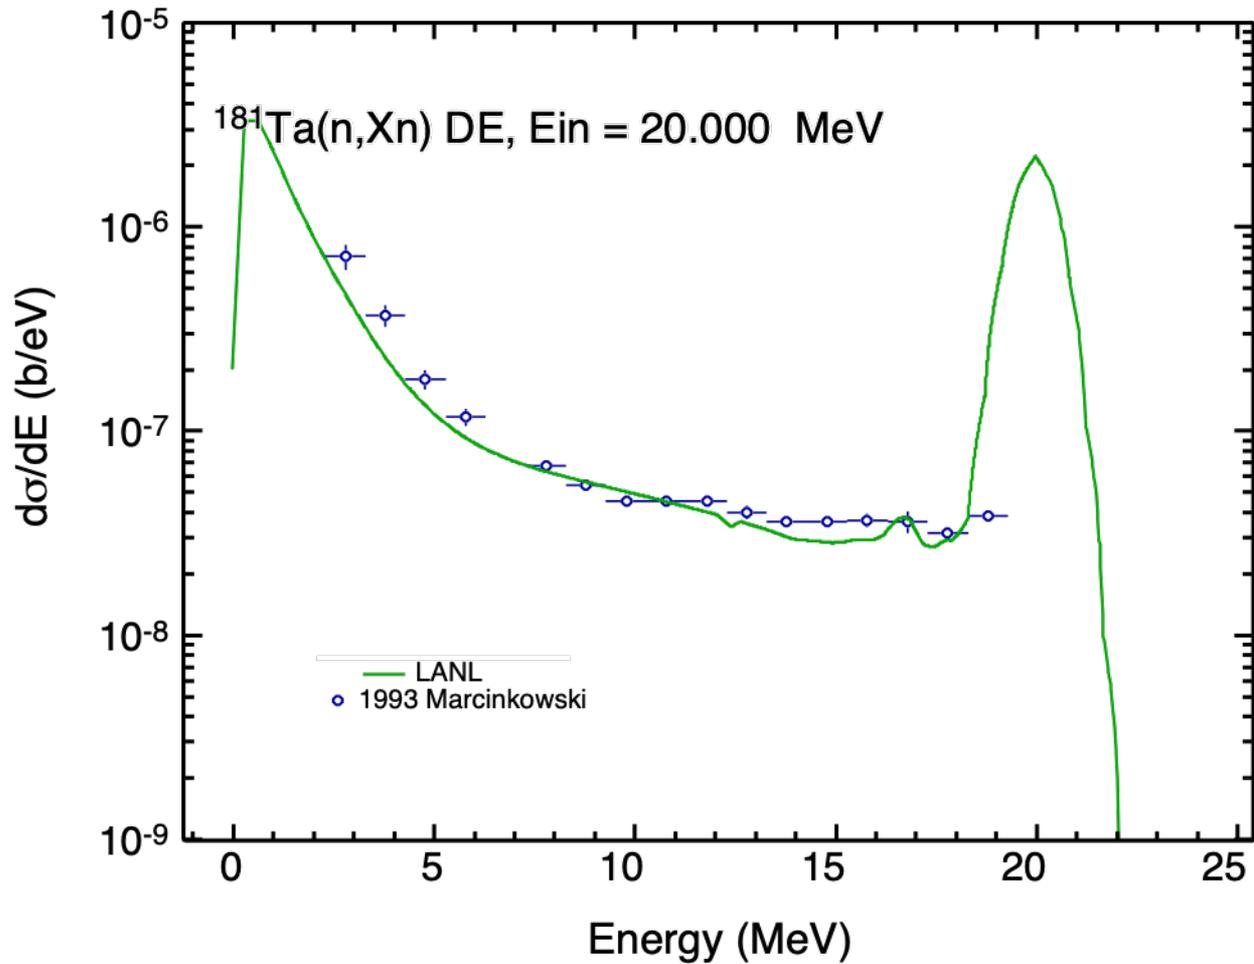

MSD $I_0 = 6.38$ MeV

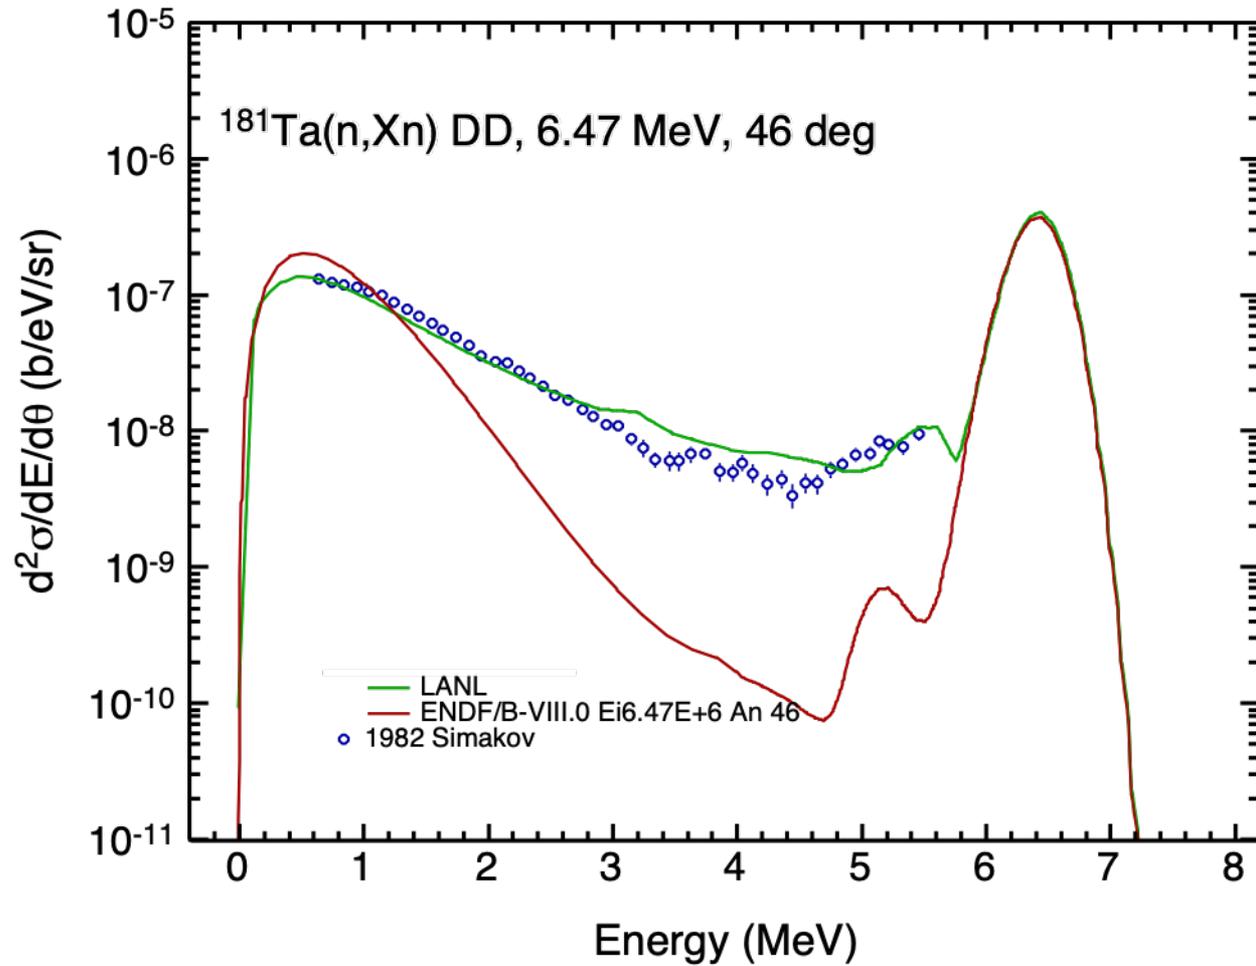

Angle integrated energy n-spectra

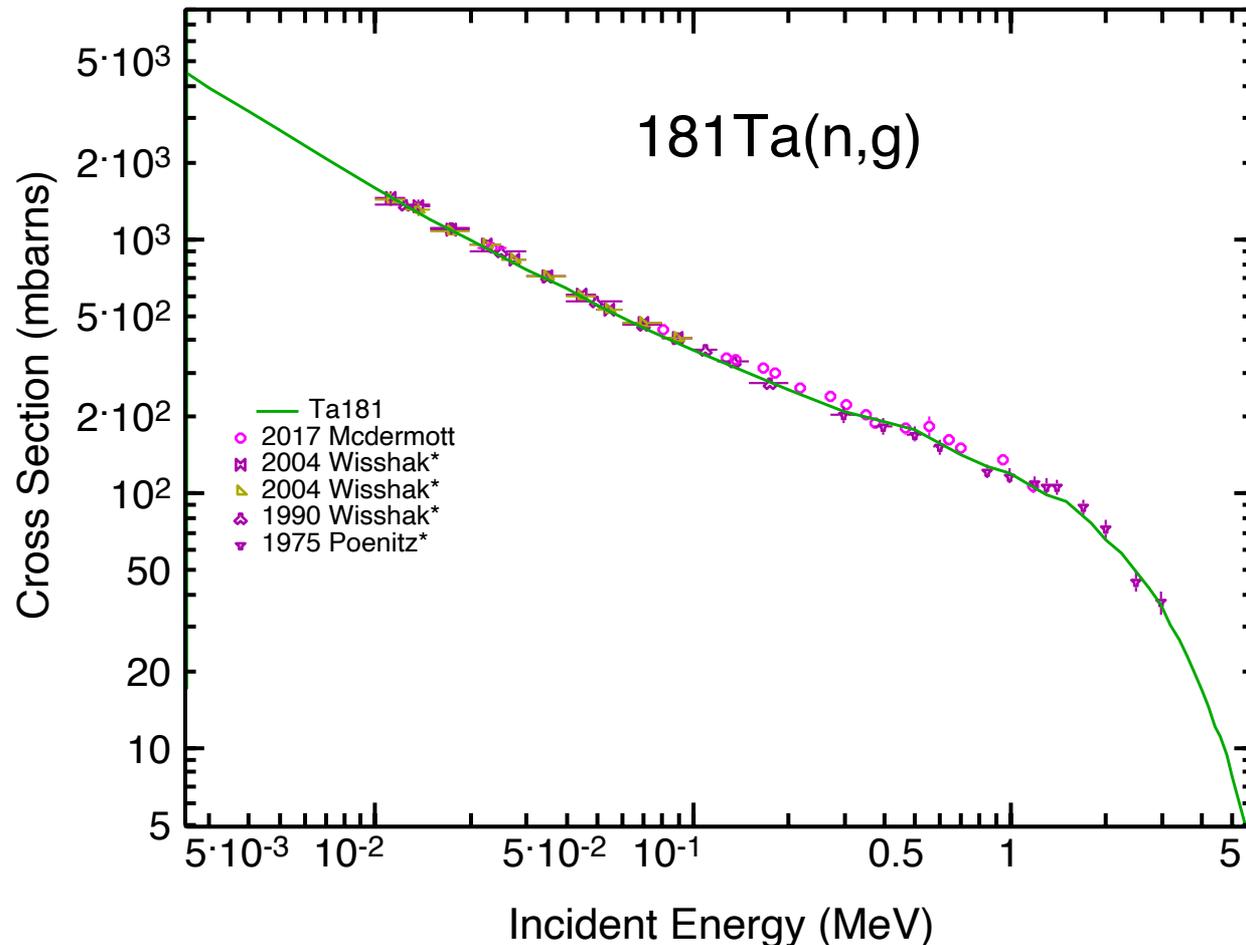

Three consistent data sets are well reproduced by the calculations.

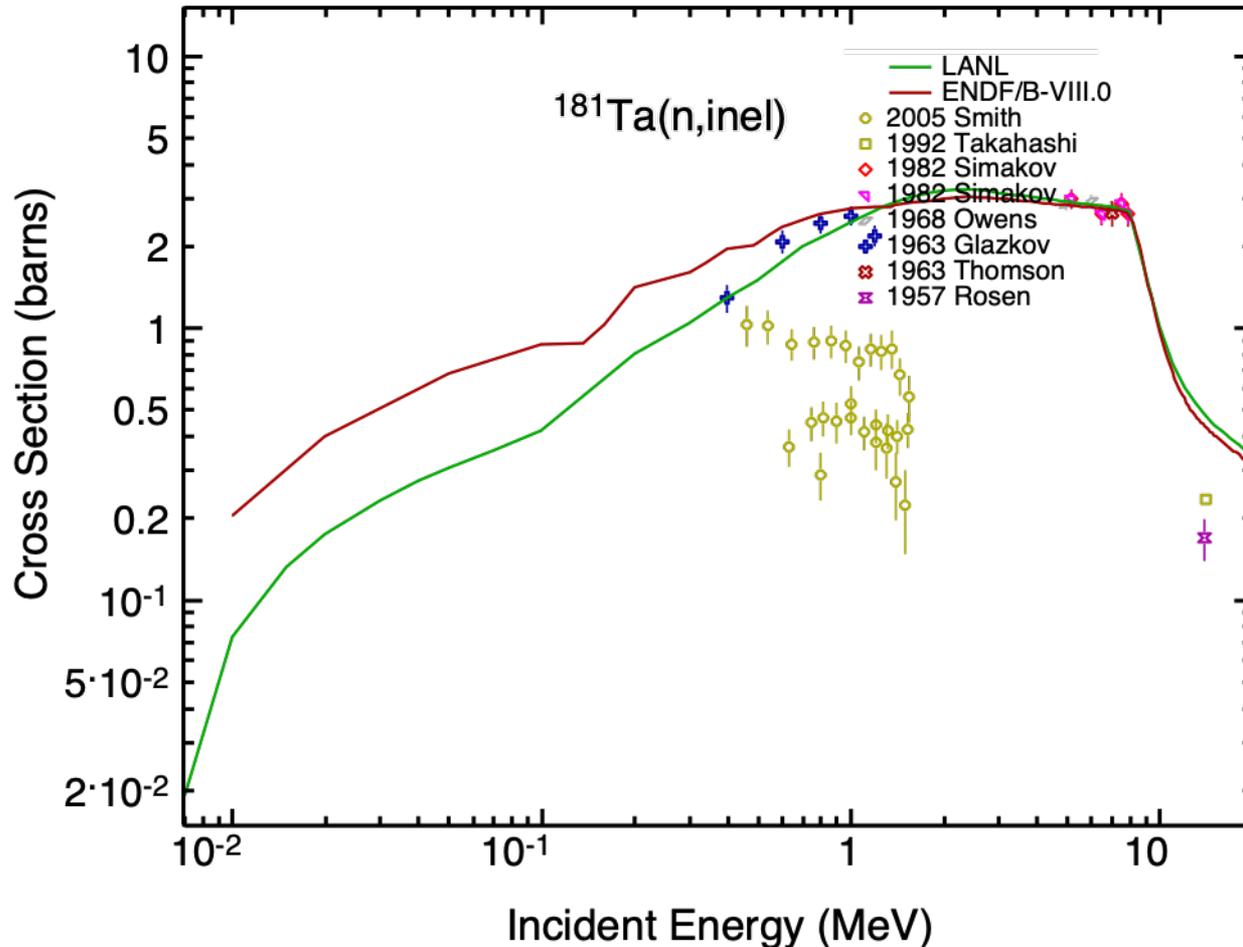

Level densities - capture, inelastic, (n,2n) x-sec, neutron & gamma spectra, ...

- Gilbert-Cameron level densities were chosen over EGSM and microscopic Hartree-Fock-Bogoliubov because the former produce better capture cross sections between 1-3 MeV, and slightly better gamma spectra.
- The effect on the neutron spectra is mixed with GC working better at incident energies around 14 MeV while EGSM has an advantage at 20 MeV.

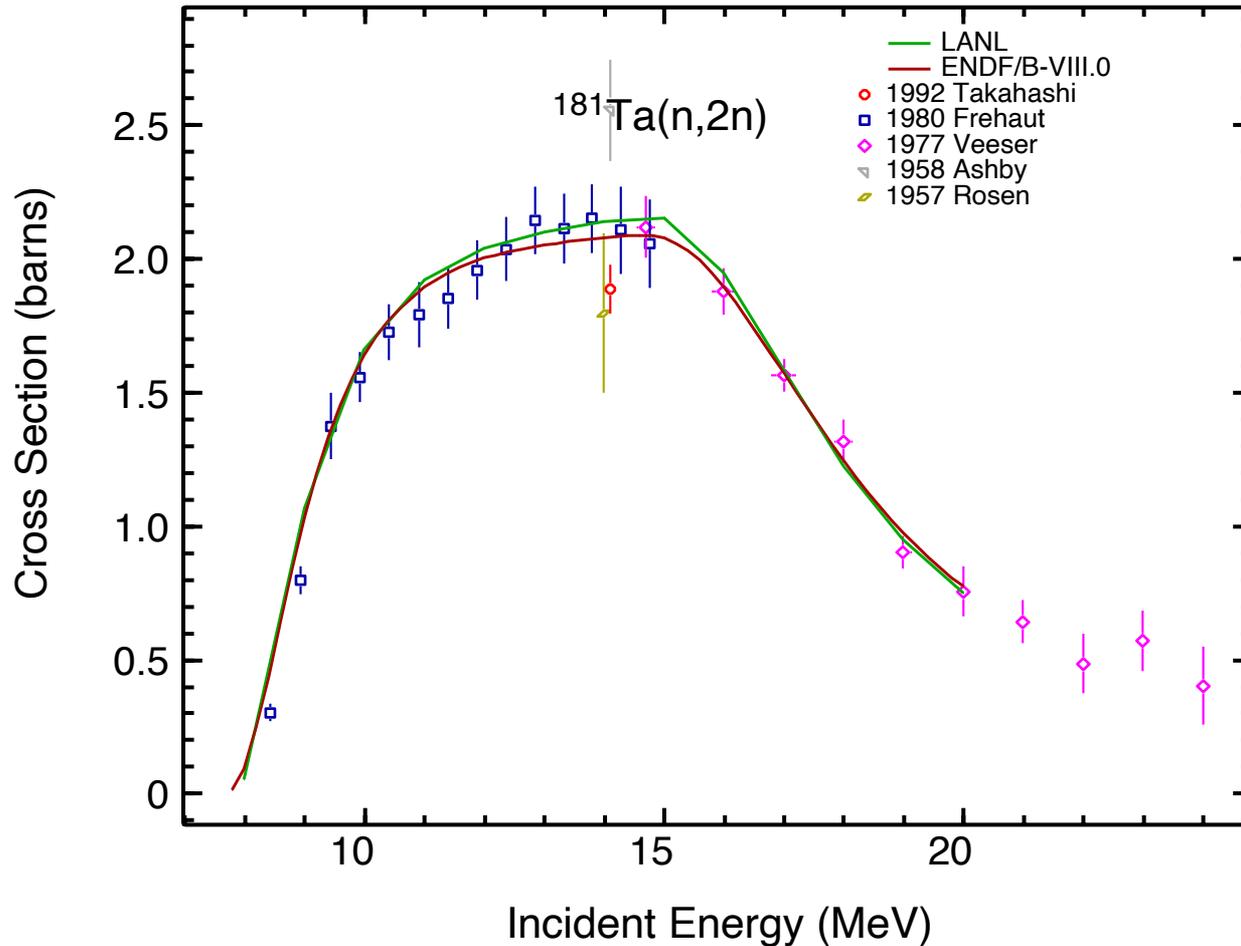

Inelastic cross sections

Ignoring data by Smith, Takahashi and Rosen as inconsistent with the overall picture.

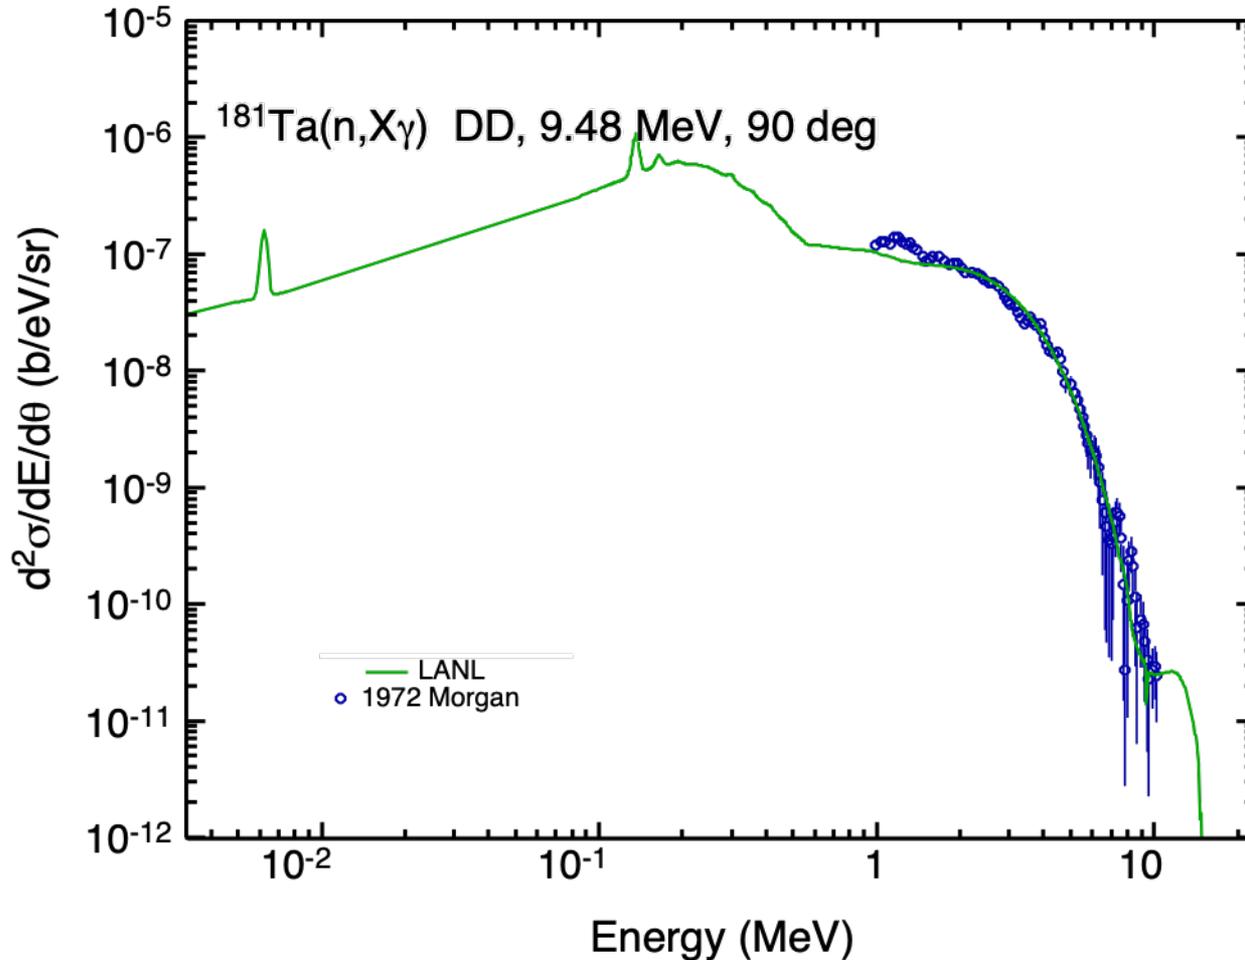

Relatively good agreement with VIII.0.

(n,2n) cross sections

Essentially identical to ENDF/B-VIII.0 but a bit better between 13-14 MeV.

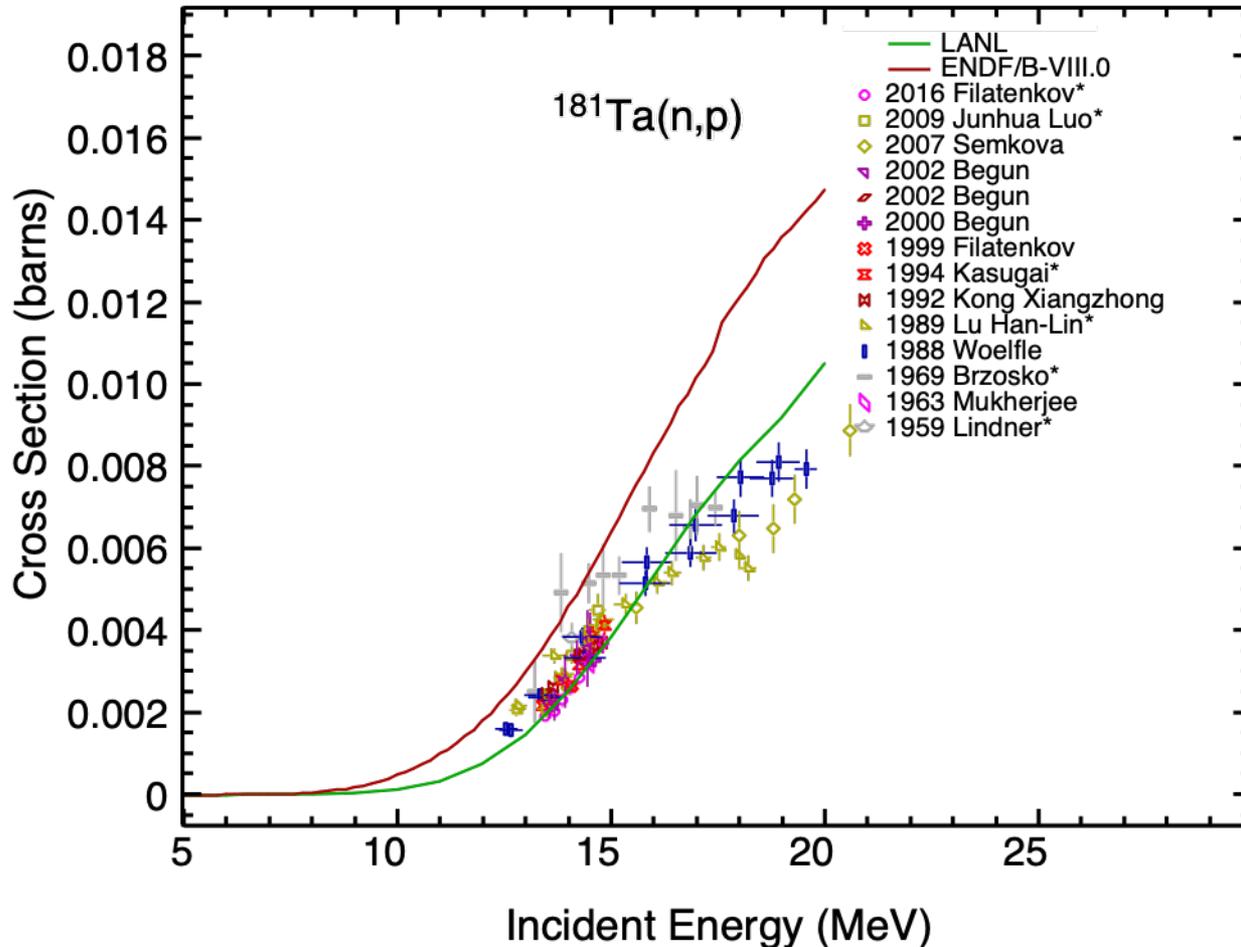

Gamma spectrum

VIII.0 gives no gamma spectra above 1 MeV of incident neutrons.

The new evaluation covers the whole energy range up to 20 MeV.

Exciton model - charged particle emission

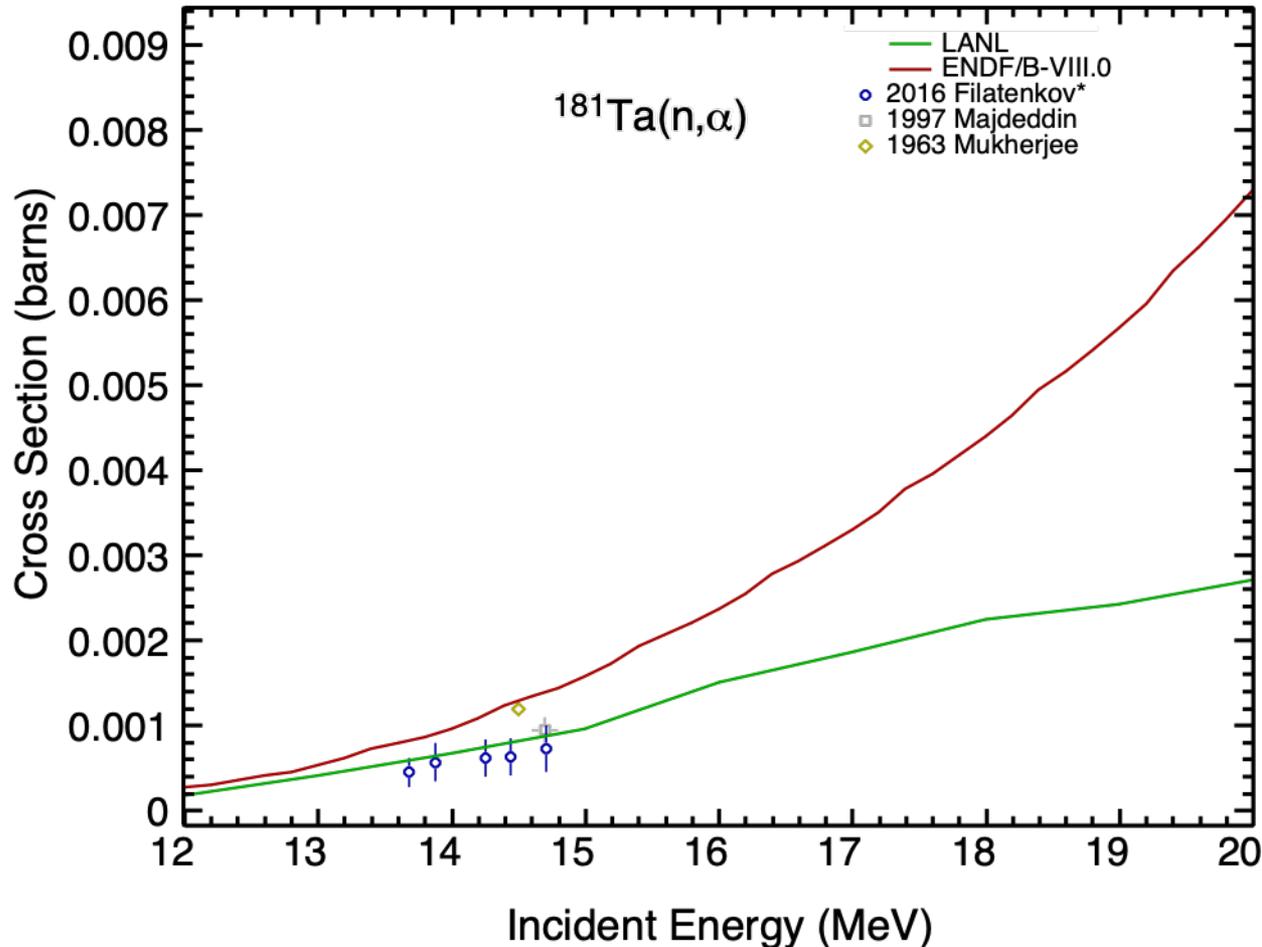

Exciton model is the only option in EMPIRE for charge-exchange reactions and cluster emission in the pre-equilibrium (PE) domain. With neutrons treated within MSD/MSC there is more freedom to adjust PE yield.

(n,p) and (n, α) reactions required reduction of the mean-free-path multiplier from the default 1.5 down to 0.8.

$$\text{MFP} = 0.8$$

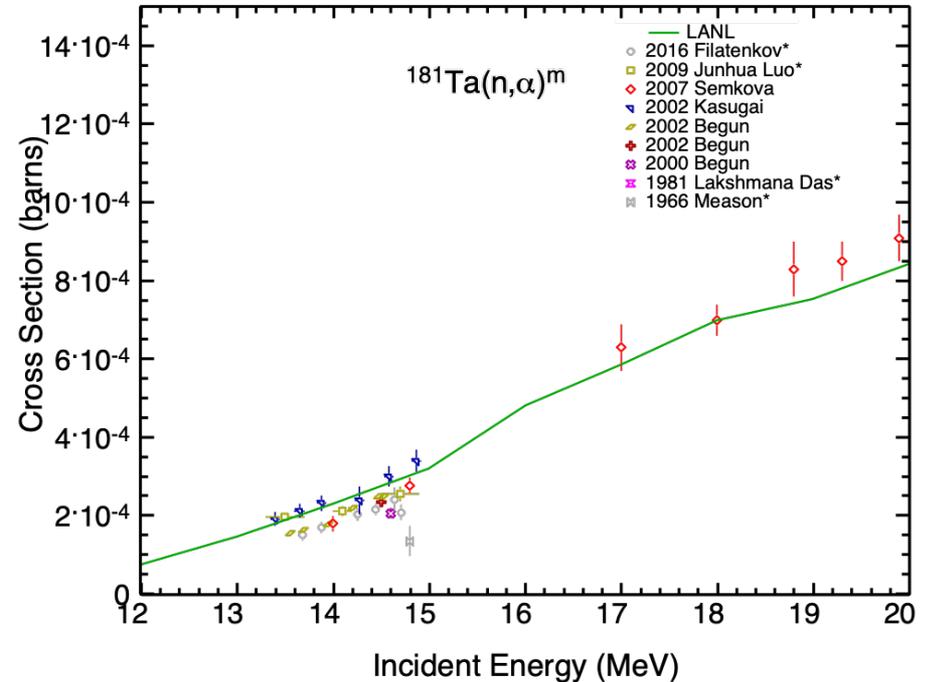

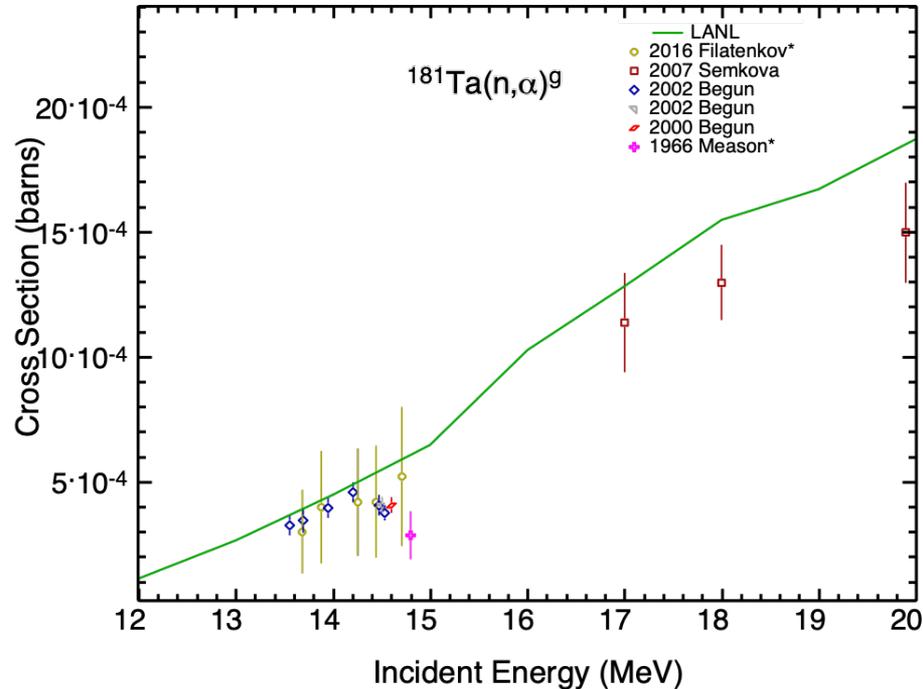

(n,p) evaluation was guided by Filatenkov's and by Semkova's data.

(n, α) reaction

VIII.0 was probably misguided by the old Mukherjee experiment.

Isomeric data confirm total (n,a) cross sections

Decay schemes completed to avoid default transitions to the g.s.

Modeling summary

- Coupled-Channels with adjusted dispersive Optical Model potential
- Multistep Direct (MSD) model for pre-equilibrium neutron emission.
- Heidelberg formulation of the Multistep Compound (MSC) model for pre-equilibrium neutron and γ -emission.
- Exciton model for pre-equilibrium proton emission.
- Exciton model with Iwamoto-Harada extension for pre-equilibrium cluster emission.
- Gilbert-Cameron model for level densities.
- Hauser-Feshbach with Moldauer width correction and BB angular distributions for compound nucleus decay.

Merge with the new RR/URR

- The two independent evaluations in RR/URR (D. Barry, J. Brown, M. Pigni, A. Lewis) and the present fast neutron-range evaluation show surprisingly good agreement at the 100 keV matching point
- We are working on solving a couple of mismatches inside URR
 - fast neutron capture lowered down to match the new resonance evaluation below 100 keV
 - work on increasing inelastic scattering in the URR region to match fast-neutron cross sections
- Current ENDF-6 does not allow for effective use of competitive width. Meantime...

We work on both evaluations to make them fully compatible in the whole URR

Conclusions

- Reliable fast-neutron evaluation can be entirely encapsulated in the reaction model and related input
- Ta181 is a particularly relevant case due to extraordinary coverage of various observables by differential experiments that offer much help and relatively little headache.
- Difference from the similar ENDF/B-VIII evaluation
 - more advanced modeling (CC OMP, MSD, MSC, decay schemes)
 - more careful selection of models and parameters
 - new experimental data
 - isomers
- Overall improved agreement with differential data and hints of better performance in integral testing
